Python Module Index
This user guide covers using CKAN’s web interface to organize, publish and find data. CKAN also has a powerful API (machine interface), which makes it easy to develop extensions and links with other information systems. The API is documented in API guide.

Some web UI features relating to site administration are available only to users with sysadmin status, and are documented in Sysadmin guide.

1.1 What is CKAN?

CKAN is a tool for making open data websites. (Think of a content management system like WordPress - but for data, instead of pages and blog posts.) It helps you manage and publish collections of data. It is used by national and local governments, research institutions, and other organizations who collect a lot of data.

Once your data is published, users can use its faceted search features to browse and find the data they need, and preview it using maps, graphs and tables - whether they are developers, journalists, researchers, NGOs, citizens, or even your own staff.

1.1.1 Datasets and resources

For CKAN purposes, data is published in units called “datasets”. A dataset is a parcel of data - for example, it could be the crime statistics for a region, the spending figures for a government department, or temperature readings from various weather stations. When users search for data, the search results they see will be individual datasets.

A dataset contains two things:

- Information or “metadata” about the data. For example, the title and publisher, date, what formats it is available in, what license it is released under, etc.

- A number of “resources”, which hold the data itself. CKAN does not mind what format the data is in. A resource can be a CSV or Excel spreadsheet, XML file, PDF document, image file, linked data in RDF format, etc. CKAN can store the resource internally, or store it simply as a link, the resource itself being elsewhere on
the web. A dataset can contain any number of resources. For example, different resources might contain the data for different years, or they might contain the same data in different formats.

**Note:** On early CKAN versions, datasets were called “packages” and this name has stuck in some places, specially internally and on API calls. Package has exactly the same meaning as “dataset”.

### 1.1.2 Users, organizations and authorization

CKAN users can register user accounts and log in. Normally (depending on the site setup), login is not needed to search for and find data, but is needed for all publishing functions: datasets can be created, edited, etc by users with the appropriate permissions.

Normally, each dataset is owned by an “organization”. A CKAN instance can have any number of organizations. For example, if CKAN is being used as a data portal by a national government, the organizations might be different government departments, each of which publishes data. Each organization can have its own workflow and authorizations, allowing it to manage its own publishing process.

An organization’s administrators can add individual users to it, with different roles depending on the level of authorization needed. A user in an organization can create a dataset owned by that organization. In the default setup, this dataset is initially private, and visible only to other users in the same organization. When it is ready for publication, it can be published at the press of a button. This may require a higher authorization level within the organization.

Datasets cannot normally be created except within organizations. It is possible, however, to set up CKAN to allow datasets not owned by any organization. Such datasets can be edited by any logged-in user, creating the possibility of a wiki-like datahub.

**Note:** The user guide covers all the main features of the web user interface (UI). In practice, depending on how the site is configured, some of these functions may be slightly different or unavailable. For example, in an official CKAN instance in a production setting, the site administrator will probably have made it impossible for users to create new organizations via the UI. You can try out all the features described at [http://demo.ckan.org](http://demo.ckan.org).

### 1.2 Using CKAN

#### 1.2.1 Registering and logging in

**Note:** Registration is needed for most publishing features and for personalization features, such as “following” datasets. It is not needed to search for and download data.

To create a user ID, use the “Register” link at the top of any page. CKAN will ask for the following:

- **Username** – choose a username using only letters, numbers, - and _ characters. For example, “jbloggs” or “joe_bloggs93”.
- **Full name** – to be displayed on your user profile
- **E-mail address** – this will not be visible to other users
- **Password** – enter the same password in both boxes
If there are problems with any of the fields, CKAN will tell you the problem and enable you to correct it. When the fields are filled in correctly, CKAN will create your user account and automatically log you in.

**Note:** It is perfectly possible to have more than one user account attached to the same e-mail address. For this reason, choose a username you will remember, as you will need it when logging in.

### 1.2.2 Features for publishers

#### Adding a new dataset

**Note:** You may need to be a member of an organization in order to add and edit datasets. See the section *Creating an organization* below. On http://demo.ckan.org, you can add a dataset without being in an organization, but dataset features relating to authorization and organizations will not be available.

**Step 1.** You can access CKAN’s “Create dataset” screen in two ways.

1. Select the “Datasets” link at the top of any page. From this, above the search box, select the “Add Dataset” button.

2. Alternatively, select the “organizations” link at the top of a page. Now select the page for the organization that should own your new dataset. Provided that you are a member of this organization, you can now select the “Add Dataset” button above the search box.

**Step 2.** CKAN will ask for the following information about your data. (The actual data will be added in step 4.)
• **Title** – this title will be unique across CKAN, so make it brief but specific. E.g. “UK population density by region” is better than “Population figures”.

• **Description** – You can add a longer description of the dataset here, including information such as where the data is from and any information that people will need to know when using the data.

• **Tags** – here you may add tags that will help people find the data and link it with other related data. Examples could be “population”, “crime”, “East Anglia”. Hit the <return> key between tags. If you enter a tag wrongly, you can use its delete button to remove it before saving the dataset.

• **License** – it is important to include license information so that people know how they can use the data. This field should be a drop-down box. If you need to use a license not on the list, contact your site administrator.

• **Organization** - If you are a member of any organizations, this drop-down will enable you to choose which one should own the dataset. Ensure the default chosen is the correct one before you proceed. (Probably most users will be in only one organization. If this is you, CKAN will have chosen your organization by default and you need not do anything.)

Note: By default, the only required field on this page is the title. However, it is good practice to include, at the minimum, a short description and, if possible, the license information. You should ensure that you choose the correct organization for the dataset, since at present, this cannot be changed later. You can edit or add to the other fields later.

**Step 3.** When you have filled in the information on this page, select the “Next: Add Data” button. (Alternatively select “Cancel” to discard the information filled in.)

**Step 4.** CKAN will display the “Add data” screen.
This is where you will add one or more “resources” which contain the data for this dataset. Choose a file or link for your data resource and select the appropriate choice at the top of the screen:

- If you are giving CKAN a link to the data, like http://example.com/mydata.csv, then select “Link to a file” or “Link to an API”. (If you don’t know what an API is, you don’t need to worry about this option - select “Link to a file”.)

- If the data to be added to CKAN is in a file on your computer, select “Upload a file”. CKAN will give you a file browser to select it.

**Step 5.** Add the other information on the page. CKAN does not require this information, but it is good practice to add it:

- **Name** – a name for this resource, e.g. “Population density 2011, CSV”. Different resources in the dataset should have different names.

- **Description** – a short description of the resource.

- **Format** – the file format of the resource, e.g. CSV (comma-separated values), XLS, JSON, PDF, etc.

**Step 6.** If you have more resources (files or links) to add to the dataset, select the “Save & add another” button. When you have finished adding resources, select “Next: Additional Info”.

**Step 7.** CKAN displays the “Additional data” screen.

- **Visibility** – a Public dataset is public and can be seen by any user of the site. A Private dataset can only be seen by members of the organization owning the dataset and will not show up in searches by other users.

- **Author** – The name of the person or organization responsible for producing the data.

- **Author e-mail** – an e-mail address for the author, to which queries about the data should be sent.

- **Maintainer / maintainer e-mail** – If necessary, details for a second person responsible for the data.
Custom fields – If you want the dataset to have another field, you can add the field name and value here. E.g. “Year of publication”. Note that if there is an extra field that is needed for a large number of datasets, you should talk to your site administrator about changing the default schema and dataset forms.

Note: Everything on this screen is optional, but you should ensure the “Visibility” is set correctly. It is also good practice to ensure an Author is named.

Changed in version 2.2: Previous versions of CKAN used to allow adding the dataset to existing groups in this step. This was changed. To add a dataset to an existing group now, go to the “Group” tab in the Dataset’s page.

Step 8. Select the ‘Finish’ button. CKAN creates the dataset and shows you the result. You have finished!

You should be able to find your dataset by typing the title, or some relevant words from the description, into the search box on any page in your CKAN instance. For more information about finding data, see the section Finding data.

Editing a dataset

You can edit the dataset you have created, or any dataset owned by an organization that you are a member of. (If a dataset is not owned by any organization, then any registered user can edit it.)

1. Go to the dataset’s page. You can find it by entering the title in the search box on any page.
2. Select the “Edit” button, which you should see above the dataset title.
3. CKAN displays the “Edit dataset” screen. You can edit any of the fields (Title, Description, Dataset, etc), change the visibility (Private/Public), and add or delete tags or custom fields. For details of these fields, see Adding a new dataset.
4. When you have finished, select the “Update dataset” button to save your changes.
Adding, deleting and editing resources

1. Go to the dataset’s “Edit dataset” page (steps 1-2 above).

2. In the left sidebar, there are options for editing resources. You can select an existing resource (to edit or delete it), or select “Add new resource”.

3. You can edit the information about the resource or change the linked or uploaded file. For details, see steps 4-5 of “Adding a new resource”, above.

4. When you have finished editing, select the button marked “Update resource” (or “Add”, for a new resource) to save your changes. Alternatively, to delete the resource, select the “Delete resource” button.

Deleting a dataset

1. Go to the dataset’s “Edit dataset” page (see “Editing a dataset”, above).

2. Select the “Delete” button.

3. CKAN displays a confirmation dialog box. To complete deletion of the dataset, select “Confirm”.

Note: The “Deleted” dataset is not completely deleted. It is hidden, so it does not show up in any searches, etc. However, by visiting the URL for the dataset’s page, it can still be seen (by users with appropriate authorization), and “undeleted” if necessary. If it is important to completely delete the dataset, contact your site administrator.
Creating an organization

In general, each dataset is owned by one organization. Each organization includes certain users, who can modify its datasets and create new ones. Different levels of access privileges within an organization can be given to users, e.g. some users might be able to edit datasets but not create new ones, or to create datasets but not publish them. Each organization has a home page, where users can find some information about the organization and search within its datasets. This allows different data publishing departments, bodies, etc to control their own publishing policies.

To create an organization:

1. Select the “Organizations” link at the top of any page.
2. Select the “Add Organization” button below the search box.
3. CKAN displays the “Create an Organization” page.
4. Enter a name for the organization, and, optionally, a description and image URL for the organization’s home page.
5. Select the “Create Organization” button. CKAN creates your organization and displays its home page. Initially, of course, the organization has no datasets.

You can now change the access privileges to the organization for other users - see Managing an organization below. You can also create datasets owned by the organization; see Adding a new dataset above.

Note: Depending on how CKAN is set up, you may not be authorized to create new organizations. In this case, if you need a new organization, you will need to contact your site administrator.
Managing an organization

When you create an organization, CKAN automatically makes you its “Admin”. From the organization’s page you should see an “Admin” button above the search box. When you select this, CKAN displays the organization admin page. This page has two tabs:

- **Info** – Here you can edit the information supplied when the organization was created (title, description and image).
- **Members** – Here you can add, remove and change access roles for different users in the organization. Note: you will need to know their username on CKAN.

By default CKAN allows members of organizations with three roles:

- **Member** – can see the organization’s private datasets
- **Editor** – can edit and publish datasets
- **Admin** – can add, remove and change roles for organization members

1.2.3 Finding data

Searching the site

To find datasets in CKAN, type any combination of search words (e.g. “health”, “transport”, etc) in the search box on any page. CKAN displays the first page of results for your search. You can:

- View more pages of results
- Repeat the search, altering some terms
• Restrict the search to datasets with particular tags, data formats, etc using the filters in the left-hand column

If there are a large number of results, the filters can be very helpful, since you can combine filters, selectively adding and removing them, and modify and repeat the search with existing filters still in place.

If datasets are tagged by geographical area, it is also possible to run CKAN with an extension which allows searching and filtering of datasets by selecting an area on a map.

Searching within an organization

If you want to look for data owned by a particular organization, you can search within that organization from its home page in CKAN.

1. Select the “Organizations” link at the top of any page.
2. Select the organization you are interested in. CKAN will display your organization’s home page.
3. Type your search query in the main search box on the page.

CKAN will return search results as normal, but restricted to datasets from the organization.

If the organization is of interest, you can opt to be notified of changes to it (such as new datasets and modifications to datasets) by using the “Follow” button on the organization page. See the section Managing your news feed below. You must have a user account and be logged in to use this feature.

Exploring datasets

When you have found a dataset you are interested and selected it, CKAN will display the dataset page. This includes

• The name, description, and other information about the dataset
• Links to and brief descriptions of each of the resources

The resource descriptions link to a dedicated page for each resource. This resource page includes information about the resource, and enables it to be downloaded. Many types of resource can also be previewed directly on the resource page. .CSV and .XLS spreadsheets are previewed in a grid view, with map and graph views also available if the data is suitable. The resource page will also preview resources if they are common image types, PDF, or HTML.

The dataset page also has two other tabs:

• Activity stream – see the history of recent changes to the dataset

• Groups – see any group associated with this dataset.

If the dataset is of interest, you can opt to be notified of changes to it by using the “Follow” button on the dataset page. See the section Managing your news feed below. You must have a user account and be logged in to use this feature.

1.2.4 Personalization

CKAN provides features to personalize the experience of both searching for and publishing data. You must be logged in to use these features.
Managing your news feed

At the top of any page, select the dashboard symbol (next to your name). CKAN displays your News feed. This shows changes to datasets that you follow, and any changed or new datasets in organizations that you follow. The number by the dashboard symbol shows the number of new notifications in your News feed since you last looked at it. As well as datasets and organizations, it is possible to follow individual users (to be notified of changes that they make to datasets).

If you want to stop following a dataset (or organization or user), go to the dataset’s page (e.g. by selecting a link to it in your News feed) and select the “Unfollow” button.

Managing your user profile

You can change the information that CKAN holds about you, including what other users see about you by editing your user profile. (Users are most likely to see your profile when you edit a dataset or upload data to an organization that they are following.) To do this, select the gearwheel symbol at the top of any page.
CKAN displays the user settings page. Here you can change:

- Your username
- Your full name
- Your e-mail address (note: this is not displayed to other users)
- Your profile text - an optional short paragraph about yourself
- Your password

Make the changes you require and then select the “Update Profile” button.

**Note:** If you change your username, CKAN will log you out. You will need to log back in using your new username.
Sysadmin guide

This guide covers the administration features of CKAN 2.0, such as managing users and datasets. These features are available via the web user interface to a user with sysadmin rights. The guide assumes familiarity with the User guide.

Certain administration tasks are not available through the web UI but need access to the server where CKAN is installed. These include the range of configuration options using the site’s “config” file, documented in Configuration Options, and those available via Command Line Interface.

**Warning:** A sysadmin user can access and edit any organizations, view and change user details, and permanently delete datasets. You should carefully consider who has access to a sysadmin account on your CKAN system.

### 2.1 Creating a sysadmin account

Normally, a sysadmin account is created as part of the process of setting up CKAN. If one does not already exist, you will need to create a sysadmin user, or give sysadmin rights to an existing user. To do this requires access to the server; see Creating a sysadmin user for details. If another organization is hosting CKAN, you will need to ask them to create a sysadmin user.

Adding more sysadmin accounts is done in the same way. It cannot be done via the web UI.

### 2.2 Customizing look and feel

Some simple customizations to customize the ‘look and feel’ of your CKAN site are available via the UI, at http://<my-ckan-url>/ckan-admin/config/.
Here you can edit the following:

**Site title**  This title is used in the HTML `<title>` of pages served by CKAN (which may be displayed on your browser’s title bar). For example if your site title is “CKAN Demo”, the home page is called “Welcome - CKAN Demo”. The site title is also used in a few other places, e.g. in the alt-text of the main site logo.

**Style**  Choose one of five colour schemes for the default theme.

**Site tag line**  This is not used in CKAN’s current default themes, but may be used in future.

**Site tag logo**  A URL for the site logo, used at the head of every page of CKAN.

**About**  Text that appears on the “about” page, `http://<my-ckan-url>/about`. You can use Markdown here. If it is left empty, a standard text describing CKAN will appear.

**Intro text**  This text appears prominently on the home page of your site.

**Custom CSS**  For simple style changes, you can add CSS code here which will be added to the `<head>` of every page.

### 2.3 Managing organizations and datasets

A sysadmin user has full access to user accounts, organizations and datasets. For example, you have access to every organization as if you were a member of that organization. Thus most management operations are done in exactly the same way as in the normal web interface.

For example, to add or delete users to an organization, change a user’s role in the organization, delete the organization or edit its description, etc, visit the organization’s home page. You will see the ‘Admin’ button as if you were a member of the organization. You can use this to perform all organization admin functions. For details, see the [User guide](#).
Similarly, to edit, update or delete a dataset, go to the dataset page and use the ‘Edit’ button. As an admin user you can see all datasets including those that are private to an organization. They will show up when doing a dataset search.

### 2.3.1 Moving a dataset between organizations

To move a dataset between organizations, visit the dataset’s Edit page. Choose the appropriate entry from the “organization” drop-down list, and press “Save”.

![CKAN Documentation Screenshot](image)

### 2.4 Permanently deleting datasets

A dataset which has been deleted is not permanently removed from CKAN; it is simply marked as ‘deleted’ and will no longer show up in search, etc. The dataset’s URL cannot be re-used for a new dataset.

To permanently delete (“purge”) a dataset:

- Navigate to the dataset’s “Edit” page, and delete it.

This page shows all deleted datasets and allows you to delete them permanently.

**Warning:** This operation cannot be reversed!
**Note:** At present, it is not possible to purge organizations or groups using the web UI. This can only be done with access to the server, by directly deleting them from CKAN’s database.

### 2.5 Managing users

To find a user’s profile, go to `http://<my-ckan-url>/user/`. You can search for users in the search box provided.

You can search by any part of the user profile, including their e-mail address. This is useful if, for example, a user has forgotten their user ID. For non-sysadmin users, the search on this page will only match public parts of the profile, so they cannot search by e-mail address.

On their user profile, you will see a “Manage” button. CKAN displays the user settings page. You can delete the user or change any of its settings, including their username, name and password.

New in version 2.2: Previous versions of CKAN didn’t allow you to delete users through the web interface.
The sections below document how to setup and maintain a CKAN site, including installing, upgrading and configuring CKAN and its features and extensions.

### 3.1 Installing CKAN

Before you can use CKAN on your own computer, you need to install it. There are three ways to install CKAN:

1. Install from an operating system package
2. Install from source
3. Install from Docker Compose

From package is the quickest and easiest way to install CKAN, but it requires Ubuntu 16.04 64-bit or Ubuntu 14.04 64-bit. **You should install CKAN from package if:**

- You want to install CKAN on an Ubuntu 16.04 or 14.04, 64-bit server, and
- you only want to run one CKAN website per server

See *Installing CKAN from package*.

**You should install CKAN from source if:**

- You want to install CKAN on a 32-bit computer, or
- You want to install CKAN on a different version of Ubuntu, not 16.04 or 14.04, or
- You want to install CKAN on another operating system (eg. RHEL, CentOS, OS X), or
- You want to run multiple CKAN websites on the same server, or
- You want to install CKAN for development

See *Installing CKAN from source*.

The provided Docker Compose configuration provides a clean and quick way to deploy a vanilla CKAN without extensions, while still allowing the addition (and customization) of extensions. This option comes with the caveat that
some further steps need to be taken to deploy a production-ready CKAN. **You should install CKAN from Docker Compose if:**

- You want to install CKAN with less effort than a source install and more flexibility than a package install, or
- You want to run or even develop extensions with the minimum setup effort, or
- You want to see whether and how CKAN, Docker and your respective infrastructure will fit together.

See *Installing CKAN with Docker Compose*.

If you’ve already setup a CKAN website and want to upgrade it to a newer version of CKAN, see *Upgrading CKAN*.

### 3.1.1 Installing CKAN from package

This section describes how to install CKAN from package. This is the quickest and easiest way to install CKAN, but it requires **Ubuntu 16.04 64-bit** or **Ubuntu 14.04 64-bit**. If you’re not using Ubuntu 16.04 64-bit or Ubuntu 14.04 64-bit, or if you’re installing CKAN for development, you should follow *Installing CKAN from source* instead.

At the end of the installation process you will end up with two running web applications, CKAN itself and the Data-Pusher, a separate service for automatically importing data to CKAN’s *DataStore extension*.

Host ports requirements:

<table>
<thead>
<tr>
<th>Service</th>
<th>Port</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>NGINX</td>
<td>80</td>
<td>Proxy</td>
</tr>
<tr>
<td>Apache2</td>
<td>8080</td>
<td>Web Server</td>
</tr>
<tr>
<td>Solr/Jetty</td>
<td>8983</td>
<td>Search</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>5432</td>
<td>Database</td>
</tr>
<tr>
<td>Redis</td>
<td>6379</td>
<td>Search</td>
</tr>
</tbody>
</table>

1. **Install the CKAN package**

On your Ubuntu system, open a terminal and run these commands to install CKAN:

1. Update Ubuntu’s package index:

   ```
   sudo apt-get update
   ```

2. Install the Ubuntu packages that CKAN requires (and ‘git’, to enable you to install CKAN extensions):

   ```
   sudo apt-get install -y nginx apache2 libapache2-mod-wsgi libpq5 redis-server git-
   ```

3. Download the CKAN package:

   - On Ubuntu 16.04:

     ```
     wget http://packaging.ckan.org/python-ckan_2.9-xenial_amd64.deb
     ```

   - On Ubuntu 14.04:

     ```
     wget http://packaging.ckan.org/python-ckan_2.9-trusty_amd64.deb
     ```

4. Install the CKAN package:

   - On Ubuntu 16.04:
sudo dpkg -i python-ckan_2.9-xenial_amd64.deb

• On Ubuntu 14.04:
  sudo dpkg -i python-ckan_2.9-trusty_amd64.deb

Note: If you get the following error it means that for some reason the Apache WSGI module was not enabled:

```
Syntax error on line 1 of /etc/apache2/sites-enabled/ckan_default:
Invalid command 'WSGISocketPrefix', perhaps misspelled or defined by a_
module not included in the server configuration
Action 'configtest' failed.
The Apache error log may have more information.
...fail!
```

You can enable it by running these commands in a terminal:

```
sudo a2enmod wsgi
sudo service apache2 restart
```

2. Install and configure PostgreSQL

Tip: You can install PostgreSQL and CKAN on different servers. Just change the `sqlalchemy.url` setting in your `/etc/ckan/default/production.ini` file to reference your PostgreSQL server.

Install PostgreSQL, running this command in a terminal:

```
sudo apt-get install -y postgresql
```

```
orphan
```

Check that PostgreSQL was installed correctly by listing the existing databases:

```
sudo -u postgres psql -l
```

Check that the encoding of databases is UTF8, if not internationalisation may be a problem. Since changing the encoding of PostgreSQL may mean deleting existing databases, it is suggested that this is fixed before continuing with the CKAN install.

Next you’ll need to create a database user if one doesn’t already exist. Create a new PostgreSQL database user called ckan_default, and enter a password for the user when prompted. You’ll need this password later:

```
sudo -u postgres createuser -S -D -R -P ckan_default
```

Create a new PostgreSQL database, called ckan_default, owned by the database user you just created:

```
sudo -u postgres createdb -O ckan_default ckan_default -E utf-8
```

Note: If PostgreSQL is run on a separate server, you will need to edit `postgresql.conf` and `pg_hba.conf`. For PostgreSQL 9.1 on Ubuntu, these files are located in `/etc/postgresql/9.1/main`.

Uncomment the `listen_addresses` parameter and specify a comma-separated list of IP addresses of the network interfaces PostgreSQL should listen on or ‘*’ to listen on all interfaces. For example,
listen_addresses = 'localhost,192.168.1.21'

Add a line similar to the line below to the bottom of `pg_hba.conf` to allow the machine running Apache to connect to PostgreSQL. Please change the IP address as desired according to your network settings.

```
host all all 192.168.1.22/32 md5
```

Edit the `sqlalchemy.url` option in your **CKAN configuration file** (/etc/ckan/default/production.ini) file and set the correct password, database and database user.

### 3. Install and configure Solr

**Tip:** You can install Solr and CKAN on different servers. Just change the `solr_url` setting in your /etc/ckan/default/production.ini file to reference your Solr server.

Install Solr, running this command in a terminal:

```
sudo apt-get install -y solr-jetty
```

The install will whirr away, then towards the end you’ll see this:

```
* Not starting jetty - edit /etc/default/jetty (or /etc/default/jetty8) and change NO_˓→START to be 0 (or comment it out).
```

**orphan**

CKAN uses Solr as its search platform, and uses a customized Solr schema file that takes into account CKAN’s specific search needs. Now that we have CKAN installed, we need to install and configure Solr.

**Note:** These instructions explain how to deploy Solr using the Jetty web server, but CKAN doesn’t require Jetty - you can deploy Solr to another web server, such as Tomcat, if that’s convenient on your operating system.

1. Edit the Jetty configuration file (/etc/default/jetty8 or /etc/default/jetty) and change the following variables:

```
NO_START=0    # (line 4)
JETTY_HOST=127.0.0.1 # (line 16)
JETTY_PORT=8983 # (line 19)
```

**Note:** This `JETTY_HOST` setting will only allow connections from the same machine. If CKAN is not installed on the same machine as Jetty/Solr you will need to change it to the relevant host or to 0.0.0.0 (and probably set up your firewall accordingly).

Start or restart the Jetty server.

For Ubuntu 16.04:

```
sudo service jetty8 restart
```

Or for Ubuntu 14.04:
sudo service jetty restart

**Note:** Ignore any warning that it wasn’t already running - some Ubuntu distributions choose not to start Jetty on install, but it’s not important.

You should now see a welcome page from Solr if you open http://localhost:8983/solr/ in your web browser (replace localhost with your server address if needed).

**Note:** If you get the message *Could not start Jetty servlet engine because no Java Development Kit (JDK) was found.* then you will have to edit the `JAVA_HOME` setting in `/etc/default/jetty` to point to your machine’s JDK install location. For example:

```bash
JAVA_HOME=/usr/lib/jvm/java-6-openjdk-amd64/
```

or:

```bash
JAVA_HOME=/usr/lib/jvm/java-6-openjdk-i386/
```

2. Replace the default `schema.xml` file with a symlink to the CKAN schema file included in the sources.

```bash
sudo mv /etc/solr/conf/schema.xml /etc/solr/conf/schema.xml.bak
sudo ln -s /usr/lib/ckan/default/src/ckan/ckan/config/solr/schema.xml /etc/solr/conf/schema.xml
```

Now restart Solr:
For Ubuntu 16.04:

```bash
sudo service jetty8 restart
```

or for Ubuntu 14.04:

```bash
sudo service jetty restart
```

Check that Solr is running by opening http://localhost:8983/solr/.

3. Finally, change the `solr_url` setting in your CKAN configuration file (/etc/ckan/default/production.ini) to point to your Solr server, for example:

```bash
solr_url=http://127.0.0.1:8983/solr
```

4. Update the configuration and initialize the database

1. Edit the CKAN configuration file (/etc/ckan/default/production.ini) to set up the following options:

   - **site_id** Each CKAN site should have a unique `site_id`, for example:

     ```bash
     ckan.site_id = default
     ```

   - **site_url** Provide the site’s URL. For example:

     ```bash
     ckan.site_url = http://demo.ckan.org
     ```

2. Initialize your CKAN database by running this command in a terminal:
3. Optionally, setup the DataStore and DataPusher by following the instructions in DataStore extension.
4. Also optionally, you can enable file uploads by following the instructions in FileStore and file uploads.

5. Restart Apache and Nginx

Restart Apache and Nginx by running this command in a terminal:

```
sudo service apache2 restart
sudo service nginx restart
```

6. You’re done!

Open http://localhost in your web browser. You should see the CKAN front page, which will look something like this:

![CKAN Front Page](image)

You can now move on to Getting started to begin using and customizing your CKAN site.
Note: The default authorization settings on a new install are deliberately restrictive. Regular users won’t be able to create datasets or organizations. You should check the Organizations and authorization documentation, configure CKAN accordingly and grant other users the relevant permissions using the sysadmin account.

### 3.1.2 Installing CKAN from source

This section describes how to install CKAN from source. Although Installing CKAN from package is simpler, it requires Ubuntu 16.04 64-bit or Ubuntu 14.04 64-bit. Installing CKAN from source works with other versions of Ubuntu and with other operating systems (e.g. RedHat, Fedora, CentOS, OS X). If you install CKAN from source on your own operating system, please share your experiences on our How to Install CKAN wiki page.

From source is also the right installation method for developers who want to work on CKAN.

1. **Install the required packages**

If you’re using a Debian-based operating system (such as Ubuntu) install the required packages with this command for Ubuntu 16.04:

```
sudo apt-get install python-dev postgresql libpq-dev python-pip python-virtualenv git-core solr-jetty openjdk-8-jdk redis-server
```

or for Ubuntu 14.04:

```
sudo apt-get install python-dev postgresql libpq-dev python-pip python-virtualenv git-core solr-jetty openjdk-6-jdk redis-server
```

If you’re not using a Debian-based operating system, find the best way to install the following packages on your operating system (see our How to Install CKAN wiki page for help):

<table>
<thead>
<tr>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Python</td>
<td>The Python programming language, v2.7</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>The PostgreSQL database system, v9.3 or newer</td>
</tr>
<tr>
<td>libpq</td>
<td>The C programmer’s interface to PostgreSQL</td>
</tr>
<tr>
<td>pip</td>
<td>A tool for installing and managing Python packages</td>
</tr>
<tr>
<td>virtualenv</td>
<td>The virtual Python environment builder</td>
</tr>
<tr>
<td>Git</td>
<td>A distributed version control system</td>
</tr>
<tr>
<td>Apache Solr</td>
<td>A search platform</td>
</tr>
<tr>
<td>Jetty</td>
<td>An HTTP server (used for Solr),</td>
</tr>
<tr>
<td>OpenJDK JDK</td>
<td>The Java Development Kit (used by Jetty)</td>
</tr>
<tr>
<td>Redis</td>
<td>An in-memory data structure store</td>
</tr>
</tbody>
</table>

2. **Install CKAN into a Python virtual environment**

Tip: If you’re installing CKAN for development and want it to be installed in your home directory, you can symlink the directories used in this documentation to your home directory. This way, you can copy-paste the example commands from this documentation without having to modify them, and still have CKAN installed in your home directory.
mkdir -p ~/ckan/lib
sudo ln -s ~/ckan/lib /usr/lib/ckan
mkdir -p ~/ckan/etc
sudo ln -s ~/ckan/etc /etc/ckan

1. Create a Python virtual environment (virtualenv) to install CKAN into, and activate it:

    sudo mkdir -p /usr/lib/ckan/default
    sudo chown `whoami` /usr/lib/ckan/default
    virtualenv --no-site-packages /usr/lib/ckan/default
    . /usr/lib/ckan/default/bin/activate

    **Important:** The final command above activates your virtualenv. The virtualenv has to remain active for the rest of the installation and deployment process, or commands will fail. You can tell when the virtualenv is active because its name appears in front of your shell prompt, something like this:

    (default) $ _

    For example, if you logout and login again, or if you close your terminal window and open it again, your virtualenv will no longer be activated. You can always reactivate the virtualenv with this command:

    . /usr/lib/ckan/default/bin/activate

2. Install the recommended setuptools version:

    pip install setuptools==36.1

3. Install the CKAN source code into your virtualenv.

    To install the latest stable release of CKAN (CKAN 2.9.0), run:

    pip install -e 'git+https://github.com/ckan/ckan.git@ckan-2.9.0#egg=ckan'

    If you’re installing CKAN for development, you may want to install the latest development version (the most recent commit on the master branch of the CKAN git repository). In that case, run this command instead:

    pip install -e 'git+https://github.com/ckan/ckan.git#egg=ckan'

    **Warning:** The development version may contain bugs and should not be used for production websites! Only install this version if you’re doing CKAN development.

4. Install the Python modules that CKAN requires into your virtualenv:

    pip install -r /usr/lib/ckan/default/src/ckan/requirements.txt

5. Deactivate and reactivate your virtualenv, to make sure you’re using the virtualenv’s copies of commands like `paster` rather than any system-wide installed copies:

    deactivate
    . /usr/lib/ckan/default/bin/activate

3. Setup a PostgreSQL database

    orphan

    Check that PostgreSQL was installed correctly by listing the existing databases:
Check that the encoding of databases is UTF8, if not internationalisation may be a problem. Since changing the encoding of PostgreSQL may mean deleting existing databases, it is suggested that this is fixed before continuing with the CKAN install.

Next you’ll need to create a database user if one doesn’t already exist. Create a new PostgreSQL database user called ckan_default, and enter a password for the user when prompted. You’ll need this password later:

```
sudo -u postgres createuser -S -D -R -P ckan_default
```

Create a new PostgreSQL database, called ckan_default, owned by the database user you just created:

```
sudo -u postgres createdb -O ckan_default ckan_default -E utf-8
```

**Note:** If PostgreSQL is run on a separate server, you will need to edit `postgresql.conf` and `pg_hba.conf`. For PostgreSQL 9.1 on Ubuntu, these files are located in `/etc/postgresql/9.1/main`.

Uncomment the `listen_addresses` parameter and specify a comma-separated list of IP addresses of the network interfaces PostgreSQL should listen on or ‘*’ to listen on all interfaces. For example,

```
listen_addresses = 'localhost,192.168.1.21'
```

Add a line similar to the line below to the bottom of `pg_hba.conf` to allow the machine running Apache to connect to PostgreSQL. Please change the IP address as desired according to your network settings.

```
host all all 192.168.1.22/32 md5
```

### 4. Create a CKAN config file

Create a directory to contain the site’s config files:

```
sudo mkdir -p /etc/ckan/default
```

```
sudo chown -R `whoami` /etc/ckan/
```

```
sudo chown -R `whoami` ~/ckan/etc
```

Create the CKAN config file:

```
paster make-config ckan /etc/ckan/default/development.ini
```

Edit the `development.ini` file in a text editor, changing the following options:

- **sqlalchemy.url** This should refer to the database we created in 3. Setup a PostgreSQL database above:

  ```ini
sqlalchemy.url = postgresql://ckan_default:pass@localhost/ckan_default
  
  Replace pass with the password that you created in 3. Setup a PostgreSQL database above.
  ```

- **Tip:** If you’re using a remote host with password authentication rather than SSL authentication, use:

  ```ini
sqlalchemy.url = postgresql://ckan_default:pass@<remotehost>/ckan_default?
˓→sslmode=disable
  ```

- **site_id** Each CKAN site should have a unique site_id, for example:

  ```ini
ckan.site_id = default
  ```

- **site_url** Provide the site’s URL (used when putting links to the site into the FileStore, notification emails etc). For example:

  ```ini
  ```

### 3.1. Installing CKAN
CKAN documentation, Release 2.8.5

ckan.site_url = http://demo.ckan.org

Do not add a trailing slash to the URL.

5. Setup Solr

CKAN uses Solr as its search platform, and uses a customized Solr schema file that takes into account CKAN’s specific search needs. Now that we have CKAN installed, we need to install and configure Solr.

Note: These instructions explain how to deploy Solr using the Jetty web server, but CKAN doesn’t require Jetty - you can deploy Solr to another web server, such as Tomcat, if that’s convenient on your operating system.

1. Edit the Jetty configuration file (/etc/default/jetty8 or /etc/default/jetty) and change the following variables:

   NO_START=0 # (line 4)
   JETTY_HOST=127.0.0.1 # (line 16)
   JETTY_PORT=8983 # (line 19)

   Note: This JETTY_HOST setting will only allow connections from the same machine. If CKAN is not installed on the same machine as Jetty/Solr you will need to change it to the relevant host or to 0.0.0.0 (and probably set up your firewall accordingly).

   Start or restart the Jetty server.

   For Ubuntu 16.04:

   sudo service jetty8 restart

   Or for Ubuntu 14.04:

   sudo service jetty restart

   Note: Ignore any warning that it wasn’t already running - some Ubuntu distributions choose not to start Jetty on install, but it’s not important.

   You should now see a welcome page from Solr if you open http://localhost:8983/solr/ in your web browser (replace localhost with your server address if needed).

   Note: If you get the message Could not start Jetty servlet engine because no Java Development Kit (JDK) was found, then you will have to edit the JAVA_HOME setting in /etc/default/jetty to point to your machine’s JDK install location. For example:

   JAVA_HOME=/usr/lib/jvm/java-6-openjdk-amd64/

   or:

   JAVA_HOME=/usr/lib/jvm/java-6-openjdk-i386/
2. Replace the default `schema.xml` file with a symlink to the CKAN schema file included in the sources.

```
sudo mv /etc/solr/conf/schema.xml /etc/solr/conf/schema.xml.bak
sudo ln -s /usr/lib/ckan/default/src/ckan/ckan/config/solr/schema.xml /
       etc/solr/conf/schema.xml
```

Now restart Solr:

For Ubuntu 16.04:

```
sudo service jetty8 restart
```

or for Ubuntu 14.04:

```
sudo service jetty restart
```

Check that Solr is running by opening `http://localhost:8983/solr/`.

3. Finally, change the `solr_url` setting in your CKAN configuration file (`/etc/ckan/default/production.ini`) to point to your Solr server, for example:

```
solr_url=http://127.0.0.1:8983/solr
```

6. Link to `who.ini`

`who.ini` (the Repoze.who configuration file) needs to be accessible in the same directory as your CKAN config file, so create a symlink to it:

```
lss /usr/lib/ckan/default/src/ckan/who.ini /etc/ckan/default/who.ini
```

7. Create database tables

Now that you have a configuration file that has the correct settings for your database, you can create the database tables:

```
cd /usr/lib/ckan/default/src/ckan
paster db init -c /etc/ckan/default/development.ini
```

You should see `Initialising DB: SUCCESS`.

**Tip:** If the command prompts for a password it is likely you haven’t set up the `sqlalchemy.url` option in your CKAN configuration file properly. See 4. Create a CKAN config file.

8. Set up the DataStore

**Note:** Setting up the DataStore is optional. However, if you do skip this step, the DataStore features will not be available and the DataStore tests will fail.

Follow the instructions in DataStore extension to create the required databases and users, set the right permissions and set the appropriate values in your CKAN config file.
9. You're done!

You can now use the Paste development server to serve CKAN from the command-line. This is a simple and lightweight way to serve CKAN that is useful for development and testing:

```
cd /usr/lib/ckan/default/src/ckan
paster serve /etc/ckan/default/development.ini
```

Open http://127.0.0.1:5000/ in a web browser, and you should see the CKAN front page.

Now that you've installed CKAN, you should:

- Run CKAN's tests to make sure that everything's working, see Testing CKAN.
- If you want to use your CKAN site as a production site, not just for testing or development purposes, then deploy CKAN using a production web server such as Apache or Nginx. See Deploying a source install.
- Begin using and customizing your site, see Getting started.

**Note:** The default authorization settings on a new install are deliberately restrictive. Regular users won't be able to create datasets or organizations. You should check the Organizations and authorization documentation, configure CKAN accordingly and grant other users the relevant permissions using the sysadmin account.

**Source install troubleshooting**

**Solr setup troubleshooting**

Solr requests and errors are logged in the web server log files.

- For Jetty servers, the log files are:

```
/var/log/jetty/<date>.stderrout.log
```

- For Tomcat servers, they're:

```
/var/log/tomcat6/catalina.<date>.log
```

**Unable to find a javac compiler**

If when running Solr it says:

```
Unable to find a javac compiler; com.sun.tools.javac.Main is not on the classpath. Perhaps JAVA_HOME does not point to the JDK.
```

See the note in 5. Setup Solr about JAVA_HOME. Alternatively you may not have installed the JDK. Check by seeing if javac is installed:

```
which javac
```

If javac isn’t installed, do:

```
sudo apt-get install openjdk-6-jdk
```

and then restart Solr:

For Ubuntu 16.04:
 sudo service jetty8 restart

or for Ubuntu 14.04:

 sudo service jetty restart

**AttributeError: `module` object has no attribute `css/main.debug.css`**

This error is likely to show up when `debug` is set to `True`. To fix this error, install frontend dependencies. See `Frontend development guidelines`.

After installing the dependencies, run `bin/less` and then start paster server again.

If you do not want to compile CSS, you can also copy the `main.css` to `main.debug.css` to get CKAN running:

```
 cp /usr/lib/ckan/default/src/ckan/ckan/public/base/css/main.css \
 /usr/lib/ckan/default/src/ckan/ckan/public/base/css/main.debug.css
```

**JSP support not configured**

This is seen occasionally with Jetty and Ubuntu 14.04. It requires a solr-jetty fix:

```
 cd /tmp
 wget https://launchpad.net/~vshn/+archive/ubuntu/solr/+files/solr-jetty-jsp-fix_1.0.2_→all.deb
 sudo dpkg -i solr-jetty-jsp-fix_1.0.2_all.deb
 sudo service jetty restart
```

### 3.1.3 Installing CKAN with Docker Compose

This chapter is a tutorial on how to install the latest CKAN (master or any stable version) with Docker Compose. The scenario shown here is one of many possible scenarios and environments in which CKAN can be used with Docker.

This chapter aims to provide a simple, yet fully customizable deployment - easier to configure than a source install, more customizable than a package install.

The discussed setup can be useful as a development / staging environment; additional care has to be taken to use this setup in production.

**Note:** Some design decisions are opinionated (see notes), which does not mean that the alternatives are any worse. Some decisions may or may not be suitable for production scenarios, e.g. the use of CKAN master. Notably, this tutorial does not use Docker Swarm; additional steps may need to be taken to adapt the setup to use Docker Swarm.

### 1. Environment

This tutorial was tested on Ubuntu 14.04 LTS and Ubuntu 16.04 LTS, respectively. The hosts can be local environments or cloud VMs. It is assumed that the user has direct access (via terminal / ssh) to the systems and root permissions.

1. **Storage**
Using a cloud based VM, external storage volumes are cheaper than VMs and easy to backup. In our use case, we use a cloud based VM with 16 GB storage, have mounted a 100 GB btrfs-formatted external storage volume, and symlinked `/var/lib/docker` to the external volume. This allows us to store the bulky and/or precious cargo – Docker images, Docker data volumes containing the CKAN databases, filestore, and config – on a cheaper service. On the other hand, a snapshotting filesystem like btrfs is ideal for rolling backups. The same cost consideration might apply to other cloud-based providers.

Note: This setup stores data in named volumes, mapped to folder locations which can be networked or local storage. An alternative would be to re-write `docker-compose.yml` to map local storage directly, bypassing named volumes. Both solutions will save data to a specified location.

Further reading: Docker Volumes.

2. Docker

Docker is installed system-wide following the official Docker CE installation guidelines.

To verify a successful Docker installation, run `docker run hello-world`. `docker version` should output versions for client and server.

3. Docker Compose

Docker Compose is installed system-wide following the official Docker Compose installation guidelines. Alternatively, Docker Compose can be installed inside a virtualenv, which would be entirely separate from the virtualenv used inside the CKAN container, and would need to be activated before running Docker Compose commands.

To verify a successful Docker Compose installation, run `docker-compose version`.

4. CKAN source

Clone CKAN into a directory of your choice:

```bash
cd /path/to/my/projects
git clone https://github.com/ckan/ckan.git
```

This will use the latest CKAN master, which may not be stable enough for production use. To use a stable version, checkout the respective tag, e.g.:

```bash
git checkout tags/ckan-2.9.0
```

2. Build Docker images

In this step we will build the Docker images and create Docker data volumes with user-defined, sensitive settings (e.g. database passwords).

1. Sensitive settings and environment variables

Copy `contrib/docker/.env.template` to `contrib/docker/.env` and follow instructions within to set passwords and other sensitive or user-defined variables. The defaults will work fine in a development environment on Linux. For Windows and OSX, the `CKAN_SITE_URL` must be updated.

Note: Related reading:

- Docker-compose .env file
- Environment variables in Compose
- Newcomers to Docker should read the excellent write-up on Docker variables by Vladislav Supalov (GitHub @th4t)
2. Build the images

Inside the CKAN directory:

```
cd contrib/docker
docker-compose up -d --build
```

For the remainder of this chapter, we assume that `docker-compose` commands are all run inside `contrib/docker`, where `docker-compose.yml` and `.env` are located.

On first runs, the postgres container could need longer to initialize the database cluster than the ckan container will wait for. This time span depends heavily on available system resources. If the CKAN logs show problems connecting to the database, restart the ckan container a few times:

```
docker-compose restart ckan
docker ps | grep ckan
docker-compose logs -f ckan
```

**Note:** Earlier versions of `ckan-entrypoint.sh` used to wait and ping the db container using detailed db credentials (host, port, user, password). While this delay sometimes worked, it also obfuscated other possible problems. However, the db cluster needs to initialize only once, and starts up quickly in subsequent runs. This setup chose the very opinionated option of doing away with the delay altogether in favour of failing early.

After this step, CKAN should be running at `CKAN_SITE_URL`.

There should be five containers running (`docker ps`):

- `ckan`: CKAN with standard extensions
- `db`: CKAN’s database, later also running CKAN’s datastore database
- `redis`: A pre-built Redis image.
- `solr`: A pre-built SolR image set up for CKAN.
- `datapusher`: A pre-built CKAN Datapusher image.

There should be four named Docker volumes (`docker volume ls | grep docker`). They will be prefixed with the Docker Compose project name (default: `docker` or value of host environment variable `COMPOSE_PROJECT_NAME`).

```
  - docker_ckan_config: home of production.ini
  - docker_ckan_home: home of ckan venv and source, later also additional CKAN extensions
  - docker_ckan_storage: home of CKAN’s filestore (resource files)
  - docker_pg_data: home of the database files for CKAN’s default and datastore databases
```

The location of these named volumes needs to be backed up in a production environment. To migrate CKAN data between different hosts, simply transfer the content of the named volumes. A detailed use case of data transfer will be discussed in step 5.

3. Convenience: paths to named volumes

The files inside named volumes reside on a long-ish path on the host. Purely for convenience, we’ll define environment variables for these paths. We’ll use a prefix `VOL_` to avoid overriding variables in `docker-compose.yml`.

### 3.1. Installing CKAN
# Find the path to a named volume

docker volume inspect docker_ckan_home | jq -c '.[] | .Mountpoint'
# "[/var/lib/docker/volumes/docker_ckan_config/_data"

export VOL_CKAN_HOME=`docker volume inspect docker_ckan_home | jq -r -c '.[] | .Mountpoint'

echo $VOL_CKAN_HOME

export VOL_CKAN_CONFIG=`docker volume inspect docker_ckan_config | jq -r -c '.[] | .Mountpoint`

echo $VOL_CKAN_CONFIG

export VOL_CKAN_STORAGE=`docker volume inspect docker_ckan_storage | jq -r -c '.[] | .Mountpoint'

echo $VOL_CKAN_STORAGE

We won’t need to access files inside docker_pg_data directly, so we’ll skip creating the shortcut. As shown further below, we can use psql from inside the ckan container to run commands against the database and import / export files from $VOL_CKAN_HOME.

3. Datastore and datapusher

To enable the datastore, the datastore database and database users have to be created before enabling the datastore and datapusher settings in the production.ini.

1. Create and configure datastore database

With running CKAN containers, execute the built-in setup scripts against the db container:

docker exec -it db sh /docker-entrypoint-initdb.d/00_create_datastore.sh

docker exec ckan /usr/local/bin/ckan-paster --plugin=ckan datastore set-permissions -
    -c /etc/ckan/production.ini | docker exec -i db psql -U ckan

The first script will create the datastore database and the datastore readonly user in the db container. The second script is the output of paster ckan set-permissions - however, as this output can change in future versions of CKAN, we set the permissions directly. The effect of these scripts is persisted in the named volume docker_pg_data.

Note: We re-use the already privileged default user of the CKAN database as read/write user for the datastore. The database user (ckan) is hard-coded, the password is supplied through the ‘.env’ variable POSTGRES_PASSWORD. A new user datastore_ro is created (and also hard-coded) as readonly user with password DATABASE_READONLY_USER. Hard-coding the database table and usernames allows to prepare the set-permissions SQL script, while not exposing sensitive information to the world outside the Docker host environment.

After this step, the datastore database is ready to be enabled in the production.ini.

2. Enable datastore and datapusher in production.ini

Edit the production.ini (note: requires sudo):

```
sudo vim $VOL_CKAN_CONFIG/production.ini
```

Add datastore datapusher to ckan.plugins and enable the datapusher option ckan.datapusher.formats.

The remaining settings required for datastore and datapusher are already taken care of:
• ckan.storage_path (/var/lib/ckan) is hard-coded in ckan-entrypoint.sh, docker-compose.yml and CKAN’s Dockerfile. This path is hard-coded as it remains internal to the containers, and changing it would have no effect on the host system.

• ckan.datastore.write_url = postgresql://ckan:POSTGRES_PASSWORD@db/datastore and ckan.datastore.read_url = postgresql://datastore:DATASTORE_READONLY_PASSWORD@db/datastore are provided by docker-compose.yml.

Restart the ckan container to apply changes to the production.ini:
```
docker-compose restart ckan
```

Now the datastore API should return content when visiting:
```
CKAN_SITE_URL/api/3/action/datastore_search?resource_id=_table_metadata
```

### 4. Create CKAN admin user

With all images up and running, create the CKAN admin user (johndoe in this example):
```
docker exec -it ckan /usr/local/bin/ckan-paster --plugin=ckan sysadmin -c /etc/ckan/production.ini add johndoe
```

Now you should be able to login to the new, empty CKAN. The admin user’s API key will be instrumental in transferring data from other instances.

### 5. Migrate data

This section illustrates the data migration from an existing CKAN instance SOURCE_CKAN into our new Docker Compose CKAN instance assuming direct (ssh) access to SOURCE_CKAN.

1. Transfer resource files

Assuming the CKAN storage directory on SOURCE_CKAN is located at /path/to/files (containing resource files and uploaded images in resources and storage), we’ll simply rsync SOURCE_CKAN’s storage directory into the named volume docker_ckptan_storage:

```
sudo rsync -Pavvr USER@SOURCE_CKAN:/path/to/files/ $VOL_CKAN_STORAGE
```

2. Transfer users

Users could be exported using the python package ckanapi, but their password hashes will be excluded. To transfer users preserving their passwords, we need to dump and restore the user table.

On source CKAN host with access to source db ckan_default, export the user table:

```
pg_dump -h CKAN_DBHOST -P CKAN_DBPORT -U CKAN_DBUSER -a -O -t user -f user.sql ckan_default
```

On the target host, make user.sql accessible to the source CKAN container. Transfer user.sql into the named volume docker_ckptan_home and chown it to the docker user:

```
rsync -Pavvr user@ckan-source-host:/path/to/user.sql $VOL_CKAN_HOME/venv/src
```

# $VOL_CKAN_HOME is owned by the user "ckan" (UID 900) as created in the CKAN Dockerfile

(continues on next page)
Now the file `user.sql` is accessible from within the `ckan` container:

```bash
docker exec -it ckan /bin/bash -c "export TERM=xterm; exec bash"
ckan@eca111c06788:/$ psql -U ckan -h db -f $CKAN_VENV/src/user.sql
```

3. Export and upload groups, orgs, datasets

Using the python package `ckanapi` we will dump orgs, groups and datasets from the source CKAN instance, then use `ckanapi` to load the exported data into the target instance. The datapusher will automatically ingest CSV resources into the datastore.

4. Rebuild search index

Trigger a Solr index rebuild:

```bash
docker exec -it ckan /usr/local/bin/ckan-paster --plugin=ckan search-index rebuild -c /etc/ckan/production.ini
```

6. Add extensions

There are two scenarios to add extensions:

- Maintainers of production instances need extensions to be part of the `ckan` image and an easy way to enable them in the `production.ini`. Automating the installation of existing extensions (without needing to change their source) requires customizing CKAN's `Dockerfile` and scripted post-processing of the `production.ini`.

- Developers need to read, modify and use version control on the extensions’ source. This adds additional steps to the maintainers’ workflow.

For maintainers, the process is in summary:

- Run a bash shell inside the running `ckan` container, download and install extension. Alternatively, add a `pip install` step for the extension into a custom CKAN Dockerfile.
- Restart `ckan` service, read logs.

1. Download and install extension from inside `ckan` container into `docker_ckan_home` volume

The process is very similar to installing extensions in a source install. The only difference is that the installation steps will happen inside the running container, and they will use the virtualenv created inside the ckan image by CKAN’s `Dockerfile`.

The downloaded and installed files will be persisted in the named volume `docker_ckan_home`.

In this example we’ll enter the running `ckan` container to install `ckanext-geoview` from source, `ckanext-showcase` from GitHub, and `ckanext-envvars` from PyPi:

```bash
# Enter the running ckan container:
docker exec -it ckan /bin/bash -c "export TERM=xterm; exec bash"
```

(continues on next page)
# Inside the running container, activate the virtualenv
source $CKAN_VENV/bin/activate & cd $CKAN_VENV/src/

# Option 1: From source
git clone https://github.com/ckan/ckanext-geoview.git
cd ckanext-geoview
pip install -r pip-requirements.txt
python setup.py install
python setup.py develop
cd ..

# Option 2: Pip install from GitHub
pip install -e "git+https://github.com/ckan/ckanext-showcase.git#egg=ckanext-showcase"

# Option 3: Pip install from PyPi
pip install ckanext-envvars

# exit the ckan container:
exit

Some extensions require database upgrades, often through paster scripts. E.g., ckanext-spatial:

# Enter the running ckan container:
docker exec -it ckan /bin/bash -c "export TERM=xterm; exec bash"

# Inside the running ckan container
source $CKAN_VENV/bin/activate & cd $CKAN_VENV/src/
git clone https://github.com/ckan/ckanext-spatial.git
cd ckanext-spatial
pip install -r pip-requirements.txt
python setup.py install & python setup.py develop
exit

# On the host
docker exec -it db psql -U ckan -f 20_postgis_permissions.sql
docker exec -it ckan /usr/local/bin/ckan-paster --plugin=ckanext-spatial spatial
    -initdb -c /etc/ckan/production.ini

sudo vim $VOL_CKAN_CONFIG/production.ini

# Inside production.ini, add to [plugins]:
spatial_metadata spatial_query
ckanext.spatial.search_backend = solr

2. Modify CKAN config
Follow the respective extension’s instructions to set CKAN config variables:
sudo vim $VOL_CKAN_CONFIG/production.ini

Todo: Demonstrate how to set production.ini settings from environment variables using ckanext-envvars.

3. Reload and debug

3.1. Installing CKAN
4. Develop extensions: modify source, install, use version control

While maintainers will prefer to use stable versions of existing extensions, developers of extensions will need access to the extensions’ source, and be able to use version control.

The use of Docker and the inherent encapsulation of files and permissions makes the development of extensions harder than a CKAN source install.

Firstly, the absence of private SSH keys inside Docker containers will make interacting with GitHub a lot harder. On the other hand, two-factor authentication on GitHub breaks BasicAuth (HTTPS, username and password) and requires a “personal access token” in place of the password.

To use version control from inside the Docker container:

- Clone the HTTPS version of the GitHub repo.
- On GitHub, create a personal access token with “full control of private repositories”.
- Copy the token code and use as password when running `git push`.

Secondly, the persisted extension source at `VOL_CKAN_HOME` is owned by the CKAN container’s `docker` user (UID 900) and therefore not writeable to the developer’s host user account by default. There are various workarounds. The extension source can be accessed from both outside and inside the container.

Option 1: Accessing the source from inside the container:

```
docker exec -it ckan /bin/bash -c "export TERM=xterm; exec bash"
source $CKAN_VENV/bin/activate && cd $CKAN_VENV/src/
# ... work on extensions, use version control ...
# in extension folder:
python setup.py install
exit
# ... edit extension settings in production.ini and restart ckan container
sudo vim $VOL_CKAN_CONFIG/production.ini
docker-compose restart ckan
```

Option 2: Accessing the source from outside the container using `sudo`:

```
sudo vim $VOL_CKAN_CONFIG/production.ini
sudo vim $VOL_CKAN_HOME/venv/src/ckanext-datawagovautheme/ckanext/datawagovautheme/
˓
```

Option 3: The Ubuntu package `bindfs` makes the write-protected volumes accessible to a system user:

```
sudo apt-get install bindfs
mkdir ~/VOL_CKAN_HOME
sudo chown -R `whoami`:docker $VOL_CKAN_HOME
sudo bindfs --map=900/`whoami` $VOL_CKAN_HOME ~/VOL_CKAN_HOME

cd ~/VOL_CKAN_HOME/venv/src

# Do this with your own extension fork
# Assumption: the host user running git clone (you) has write access to the repository
git clone https://github.com/parksandwildlife/ckanext-datawagovautheme.git

# ... change files, use version control...
```
Changes in HTML templates and CSS will be visible right away. For changes in code, we’ll need to unmount the directory, change ownership back to the ckan user, and follow the previous steps to `python setup.py install` and `pip install -r requirements.txt` from within the running container, modify the `production.ini` and restart the container:

```
sudo umount ~/VOL_CKAN_HOME
sudo chown -R 900:900 $VOL_CKAN_HOME
# Follow steps a-c
```

**Note:** Mounting host folders as volumes instead of using named volumes may result in a simpler development workflow. However, named volumes are Docker’s canonical way to persist data. The steps shown above are only some of several possible approaches.

### 7. Environment variables

Sensitive settings can be managed in (at least) two ways, either as environment variables, or as Docker secrets. This section illustrates the use of environment variables provided by the Docker Compose `.env` file.

This section is targeted at CKAN maintainers seeking a deeper understanding of variables, and at CKAN developers seeking to factor out settings as new `.env` variables.

Variable substitution propagates as follows:

- `.env.template` holds the defaults and the usage instructions for variables.
- The maintainer copies `.env` from `.env.template` and modifies it following the instructions.
- Docker Compose interpolates variables in `docker-compose.yml` from `.env`.
- Docker Compose can pass on these variables to the containers as build time variables (when building the images) and / or as run time variables (when running the containers).
- `ckan-entrypoint.sh` has access to all run time variables of the ckan service.
- `ckan-entrypoint.sh` injects environment variables (e.g. `CKAN_SQLALCHEMY_URL`) into the running ckan container, overriding the CKAN config variables from `production.ini`.

See [Configuration Options](#configuration-options) for a list of environment variables (e.g. `CKAN_SQLALCHEMY_URL`) which CKAN will accept to override `production.ini`.

After adding new or changing existing `.env` variables, locally built images and volumes may need to be dropped and rebuilt. Otherwise, docker will re-use cached images with old or missing variables:

```
docker-compose down
docker-compose up -d --build
```

# if that didn't work, try:
```
docker rmi $(docker images -q -f dangling=true)
docker-compose up -d --build
```

# if that didn't work, try:
```
docker rmi $(docker images -q -f dangling=true)
docker volume prune
docker-compose up -d --build
```
**Warning:** Removing named volumes will destroy data. `docker volume prune` will delete any volumes not attached to a running(!) container. Backup all data before doing this in a production setting.

### 8. Steps towards production

As mentioned above, some design decisions may not be suitable for a production setup.

A possible path towards a production-ready environment is:

- Use the above setup to build docker images.
- Add and configure extensions.
- Make sure that no sensitive settings are hard-coded inside the images.
- Push the images to a docker repository.
- Create a separate “production” `docker-compose.yml` which uses the custom built images.
- Run the “production” `docker-compose.yml` on the production server with appropriate settings.
- Transfer production data into the new server as described above using volume orchestration tools or transferring files directly.
- Bonus: contribute a write-up of working production setups to the CKAN documentation.

### 3.1.4 Deploying a source install

Once you’ve installed CKAN from source by following the instructions in *Installing CKAN from source*, you can follow these instructions to deploy your CKAN site using a production web server (Apache), so that it’s available to the Internet.

**Note:** If you installed CKAN from package you don’t need to follow this section, your site is already deployed using Apache and modwsgi as described below.

Because CKAN uses WSGI, a standard interface between web servers and Python web applications, CKAN can be used with a number of different web server and deployment configurations including:

- Apache with the modwsgi Apache module proxied with Nginx for caching
- Apache with the modwsgi Apache module
- Apache with paster and reverse proxy
- Nginx with paster and reverse proxy
- Nginx with uwsgi

This guide explains how to deploy CKAN using Apache and modwsgi and proxied with Nginx on an Ubuntu server. These instructions have been tested on Ubuntu 12.04.

If run into any problems following these instructions, see *Troubleshooting* below.

#### 1. Create a production.ini File

Create your site’s `production.ini` file, by copying the `development.ini` file you created in *Installing CKAN from source* earlier:
2. Install Apache, modwsgi, modrpa

Install Apache (a web server), modwsgi (an Apache module that adds WSGI support to Apache), and modrpa (an Apache module that sets the right IP address when there is a proxy forwarding to Apache):

```
sudo apt-get install apache2 libapache2-mod-wsgi libapache2-mod-rpaf
```

3. Install Nginx

Install Nginx (a web server) which will proxy the content from Apache and add a layer of caching:

```
sudo apt-get install nginx
```

4. Install an email server

If one isn’t installed already, install an email server to enable CKAN’s email features (such as sending traceback emails to sysadmins when crashes occur, or sending new activity email notifications to users). For example, to install the Postfix email server, do:

```
sudo apt-get install postfix
```

When asked to choose a Postfix configuration, choose Internet Site and press return.

5. Create the WSGI script file

Create your site’s WSGI script file /etc/ckan/default/apache.wsgi with the following contents:

```python
import os
activate_this = os.path.join('/usr/lib/ckan/default/bin/activate_this.py')
execfile(activate_this, dict(__file__=activate_this))

from paste.deploy import loadapp
config_filepath = os.path.join(os.path.dirname(os.path.abspath(__file__)), 'production.ini')
from paste.script.util.logging_config import fileConfig
fileConfig(config_filepath)
application = loadapp('config:%s' % config_filepath)
```

The modwsgi Apache module will redirect requests to your web server to this WSGI script file. The script file then handles those requests by directing them on to your CKAN instance (after first configuring the Python environment for CKAN to run in).

6. Create the Apache config file

Create your site’s Apache config file at /etc/apache2/sites-available/ckan_default.conf, with the following contents:

```xml
<VirtualHost 127.0.0.1:8080>
    ServerName default.ckanhosted.com
    ServerAlias www.default.ckanhosted.com
    WSGIScriptAlias / /etc/ckan/default/apache.wsgi
</VirtualHost>
```
# Pass authorization info on (needed for rest api).
WSGIPassAuthorization On

# Deploy as a daemon (avoids conflicts between CKAN instances).
WSGIDaemonProcess ckan_default display-name=ckan_default processes=2,
threads=15

WSGISProcessGroup ckan_default

ErrorLog /var/log/apache2/ckan_default.error.log
CustomLog /var/log/apache2/ckan_default.custom.log combined

<IfModule mod_rpaf.c>
  RPAFenable On
  RPAFsethostname On
  RPAFproxy_ips 127.0.0.1
</IfModule>

<Directory />
  Require all granted
</Directory>

</VirtualHost>

Replace default.ckanhosted.com and www.default.ckanhosted.com with the domain name for your site.

**Note:** If you are running Apache 2.2 or lower (eg on Ubuntu 12.04), remove this directive, as it is not supported:

```
<Directory />
  Require all granted
</Directory>
```

This tells the Apache modwsgi module to redirect any requests to the web server to the WSGI script that you created above. Your WSGI script in turn directs the requests to your CKAN instance.

7. Modify the Apache ports.conf file

Open /etc/apache2/ports.conf. We need to replace the default port 80 with the 8080 one.

- On Apache 2.4 (eg Ubuntu 14.04 or RHEL 7):

  Replace this line:

  ```
  Listen 80
  ```

  With this one:

  ```
  Listen 8080
  ```

- On Apache 2.2 (eg Ubuntu 12.04 or RHEL 6):

  Replace these lines:
NameVirtualHost *:80
Listen 80

With these ones:
NameVirtualHost *:8080
Listen 8080

8. Create the Nginx config file

Create your site’s Nginx config file at /etc/nginx/sites-available/ckan, with the following contents:

```nginx
proxy_cache_path /tmp/nginx_cache levels=1:2 keys_zone=cache:30m max_size=250m;
proxy_temp_path /tmp/nginx_proxy 1 2;
server {
    client_max_body_size 100M;
    location / {
        proxy_pass http://127.0.0.1:8080/;
        proxy_set_header X-Forwarded-For $remote_addr;
        proxy_set_header Host $host;
        proxy_cache cache;
        proxy_cache_bypass $cookie_auth_tkt;
        proxy_no_cache $cookie_auth_tkt;
        proxy_cache_valid 30m;
        proxy_cache_key $host$scheme$proxy_host$request_uri;
        # In emergency comment out line to force caching
        # proxy_ignore_headers X-Accel-Expires Expires Cache-Control;
    }
}
```

9. Enable your CKAN site

To prevent conflicts, disable your default nginx and apache sites. Finally, enable your CKAN site in Apache:

```
sudo a2ensite ckan_default
sudo a2dissite 000-default
sudo rm -vi /etc/nginx/sites-enabled/default
sudo ln -s /etc/nginx/sites-available/ckan /etc/nginx/sites-enabled/ckan_
    →default
sudo service apache2 reload
sudo service nginx reload
```

You should now be able to visit your server in a web browser and see your new CKAN instance.

10. Setup a worker for background jobs

CKAN uses asynchronous Background jobs for long tasks. These jobs are executed by a separate process which is called a worker.

To run the worker in a robust way, install and configure Supervisor.
Troubleshooting

Default Apache welcome page

If you see a default Apache welcome page where your CKAN front page should be, it may be because the default Apache config file is overriding your CKAN config file (both use port 80), so disable it and restart Apache:

```sh
sudo a2dissite default
sudo service apache2 reload
```

403 Forbidden and 500 Internal Server Error

If you see a 403 Forbidden or 500 Internal Server Error page where your CKAN front page should be, you may have a problem with your unix file permissions. The Apache web server needs to have permission to access your WSGI script file and all of its parent directories. The permissions of the file should look like `-rw-r--r--` and the permissions of each of its parent directories should look like `drwxr-xr-x`.

 IOError: sys.stdout access restricted by mod_wsgi

If you’re getting 500 Internal Server Error pages and you see `IOError: sys.stdout access restricted by mod_wsgi` in your log files, it means that something in your WSGI application (e.g. your WSGI script file, your CKAN instance, or one of your CKAN extensions) is trying to print to stdout, for example by using standard Python print statements. WSGI applications are not allowed to write to stdout. Possible solutions include:

1. Remove the offending print statements. One option is to replace print statements with statements like `print >> sys.stderr, "...

2. Redirect all print statements to stderr:

   ```py
   import sys
   sys.stdout = sys.stderr
   ```

3. Allow your application to print to stdout by putting `WSGIRestrictStdout Off` in your Apache config file (not recommended).

Also see https://code.google.com/p/modwsgi/wiki/ApplicationIssues

Log files

In general, if it’s not working look in the log files in /var/log/apache2 for error messages. ckan_default.error.log should be particularly interesting.

modwsgi wiki

Some pages on the modwsgi wiki have some useful information for troubleshooting modwsgi problems:

- https://code.google.com/p/modwsgi/wiki/ApplicationIssues
3.2 Upgrading CKAN

This document describes the different types of CKAN release, and explains how to upgrade a site to a newer version of CKAN.

See also:
- Changelog  The changelog lists all CKAN releases and the main changes introduced in each release.
- Doing a CKAN release  Documentation of the process that the CKAN developers follow to do a CKAN release.

3.2.1 CKAN releases

CKAN follows a predictable release cycle so that users can depend on stable releases of CKAN, and can plan their upgrades to new releases.

Each release has a version number of the form M.m (eg. 2.1) or M.m.p (eg. 1.8.2), where M is the major version, m is the minor version and p is the patch version number. There are three types of release:

**Major Releases**  Major releases, such as CKAN 1.0 and CKAN 2.0, increment the major version number. These releases contain major changes in the CKAN code base, with significant refactorings and breaking changes, for instance in the API or the templates. These releases are very infrequent.

**Minor Releases**  Minor releases, such as CKAN 1.8 and CKAN 2.1, increment the minor version number. These releases are not as disruptive as major releases, but backwards-incompatible changes may be introduced in minor releases. The Changelog will document any breaking changes. We aim to release a minor version of CKAN roughly every three months.

**Patch Releases**  Patch releases, such as CKAN 1.8.1 or CKAN 2.0.1, increment the patch version number. These releases do not break backwards-compatibility, they include only bug fixes and security fixes, ensured to be non-breaking. Patch releases do not contain:

- Database schema changes or migrations
- Function interface changes
- Plugin interface changes
- New dependencies (unless absolutely necessary)
- Big refactorings or new features in critical parts of the code

**Note:** Users should always run the latest patch release for the minor release they are on, as patch releases contain important bug fixes and security updates. Because patch releases don’t include backwards incompatible changes, the upgrade process (as described in Upgrading a CKAN 2 package install to a new patch release) should be straightforward.

Outdated patch releases will no longer be supported after a newer patch release has been released. For example once CKAN 2.0.2 has been released, CKAN 2.0.1 will no longer be supported.

Releases are announced on the ckan-announce mailing list, a low-volume list that CKAN instance maintainers can subscribe to in order to be up to date with upcoming releases.
3.2.2 Upgrading CKAN

This section will walk you through the steps to upgrade your CKAN site to a newer version of CKAN.

**Note:** Before upgrading your version of CKAN you should check that any custom templates or extensions you’re using work with the new version of CKAN. For example, you could install the new version of CKAN in a new virtual environment and use that to test your templates and extensions.

**Note:** You should also read the [Changelog](#) to see if there are any extra notes to be aware of when upgrading to the new version.

### 1. Backup your database

You should always backup your CKAN database before upgrading CKAN. If something goes wrong with the CKAN upgrade you can use the backup to restore the database to its pre-upgrade state.

1. Activate your virtualenv and switch to the ckan source directory, e.g.:
   ```bash
   . /usr/lib/ckan/default/bin/activate
   cd /usr/lib/ckan/default/src/ckan
   ```

2. **Backup your CKAN database**

### 2. Upgrade CKAN

The process of upgrading CKAN differs depending on whether you have a package install or a source install of CKAN, and whether you’re upgrading to a **major, minor or patch release** of CKAN. Follow the appropriate one of these documents:

#### Upgrading a CKAN 1 package install to CKAN 2.x

**Note:** If you want to upgrade a CKAN 1.x package install to a newer version of CKAN 1 (as opposed to upgrading to CKAN 2), see the documentation relevant to the old CKAN packaging system.

The CKAN 2.x packages require Ubuntu 16.04 64-bit or 14.04 64-bit, whereas previous CKAN packages used Ubuntu 10.04. CKAN 2.x also introduces many backwards-incompatible feature changes (see [the changelog](#)). So it’s not possible to automatically upgrade to a CKAN 2.x package install.

However, you can install CKAN 2.x (either on the same server that contained your CKAN 1.x site, or on a different machine) and then manually migrate your database and any custom configuration, extensions or templates to your new CKAN 2.x site. We will outline the main steps for migrating below.

1. **Create a dump** of your CKAN 1.x database.

2. If you want to install CKAN 2.x on the same server that your CKAN 1.x site was on, uninstall the CKAN 1.x package first:

   ```bash
   sudo apt-get autoremove ckan
   ```
3. Install CKAN 2.x, either from a package install if you have Ubuntu 16.04 or 14.04 64-bit, or from a source install otherwise.

4. Load your database dump from CKAN 1.x into CKAN 2.x. This will migrate all of your datasets, resources, groups, tags, user accounts, and other data to CKAN 2.x. Your database schema will be automatically upgraded, and your search index rebuilt.

First, activate your CKAN virtual environment and change to the ckan dir:

```
. /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src/ckan
```

Now load your database dump into CKAN 2.x. If you’ve installed CKAN 2.x on a different machine from 1.x, first copy the database dump file to that machine.

5. If you had any custom config settings in your CKAN 1.x instance that you want to copy across to your CKAN 2.x instance, then update your CKAN 2.x /etc/ckan/default/production.ini file with these config settings. Note that not all CKAN 1.x config settings are still supported in CKAN 2.x, see Configuration Options for details.

In particular, CKAN 2.x introduces an entirely new authorization system and any custom authorization settings you had in CKAN 1.x will have to be reconsidered for CKAN 2.x. See Organizations and authorization for details.

6. If you had any extensions installed in your CKAN 1.x instance that you also want to use with your CKAN 2.x instance, install those extensions in CKAN 2.x. Not all CKAN 1.x extensions are compatible with CKAN 2.x. Check each extension’s documentation for CKAN 2.x compatibility and install instructions.

7. If you had any custom templates in your CKAN 1.x instance, these will need to be adapted before they can be used with CKAN 2.x. CKAN 2.x introduces an entirely new template system based on Jinja2 rather than on Genshi. See Theming guide for details.

**Upgrading a CKAN 2 package install to a new patch release**

**Note:** Before upgrading CKAN you should check the compatibility of any custom themes or extensions you’re using, check the changelog, and backup your database. See Upgrading CKAN.

Patch releases are distributed in the same package as the minor release they belong to, so for example CKAN 2.0, 2.0.1, 2.0.2, etc. will all be installed using the CKAN 2.0 package (python-ckan_2.0_amd64.deb):

1. Download the CKAN package:

   ```
   wget http://packaging.ckan.org/python-ckan_2.0_amd64.deb
   ```

   You can check the actual CKAN version from a package running the following command:

   ```
   dpkg --info python-ckan_2.0_amd64.deb
   ```

   Look for the Version field in the output:

   ```
   ...
   Package: python-ckan
   Version: 2.0.1-3
   ...
   ```

2. Install the package with the following command:
Your CKAN instance should be upgraded straight away.

**Note:** If you have changed the Apache, Nginx or who.ini configuration files, you will get a prompt like the following, asking whether to keep your local changes or replace the files. You generally would like to keep your local changes (option N, which is the default), but you can look at the differences between versions by selecting option D:

```
Configuration file `/etc/apache2/sites-available/ckan_default'
===> File on system created by you or by a script.
===> File also in package provided by package maintainer.
What would you like to do about it ? Your options are:
   Y or I : install the package maintainer's version
   N or O : keep your currently-installed version
   D      : show the differences between the versions
   Z      : start a shell to examine the situation
The default action is to keep your current version.
*** ckan_default (Y/I/N/O/D/Z) [default=N] ?
```

Your local CKAN configuration file in /etc/ckan/default will not be replaced.

**Note:** The install process will uninstall any existing CKAN extensions or other libraries located in the src directory of the CKAN virtualenv. To enable them again, the installation process will iterate all folders in the src directory, reinstall the requirements listed in pip-requirements.txt and requirements.txt files and run python setup.py develop for each. If you are using a custom extension which does not use this requirements file names or is located elsewhere, you will need to manually reenable it.

**Note:** When upgrading from 2.0 to 2.0.1 you may see some vdm related warnings when installing the package:

```
dpkg: warning: unable to delete old directory '/usr/lib/ckan/default/src/vdm':
  →Directory not empty
```

These are due to vdm not longer being installed from source. You can ignore them and delete the folder manually if you want.

3. Finally, restart Apache and Nginx:

   ```
sudo service apache2 restart
sudo service nginx restart
```

4. You’re done!

You should now be able to visit your CKAN website in your web browser and see that it’s running the new version of CKAN.

**Upgrading a CKAN 2 package install to a new minor release**
Note: Before upgrading CKAN you should check the compatibility of any custom themes or extensions you’re using, check the changelog, and backup your database. See Upgrading CKAN.

Each minor release is distributed in its own package, so for example CKAN 2.0.x and 2.1.x will be installed using the python-ckan_2.0_amd64.deb and python-ckan_2.1_amd64.deb packages respectively.

1. Download the CKAN package for the new minor release you want to upgrade to (replace the version number with the relevant one):

```bash
wget http://packaging.ckan.org/python-ckan_2.1_amd64.deb
```

2. Install the package with the following command:

```bash
sudo dpkg -i python-ckan_2.1_amd64.deb
```

Note: If you have changed the Apache, Nginx or who.ini configuration files, you will get a prompt like the following, asking whether to keep your local changes or replace the files. You generally would like to keep your local changes (option N, which is the default), but you can look at the differences between versions by selecting option D:

```
Configuration file `/etc/apache2/sites-available/ckan_default'
==> File on system created by you or by a script.
==> File also in package provided by package maintainer.
What would you like to do about it? Your options are:
Y or I : install the package maintainer's version
N or O : keep your currently-installed version
D : show the differences between the versions
Z : start a shell to examine the situation
The default action is to keep your current version.
*** ckan_default (Y/I/N/O/D/Z) [default=N] ?
```

Your local CKAN configuration file in /etc/ckan/default will not be replaced.

Note: The install process will uninstall any existing CKAN extensions or other libraries located in the src directory of the CKAN virtualenv. To enable them again, the installation process will iterate over all folders in the src directory, reinstall the requirements listed in pip-requirements.txt and requirements.txt files and run python setup.py develop for each. If you are using a custom extension which does not use this requirements file name or is located elsewhere, you will need to manually reinstall it.

3. If there have been changes in the database schema (check the Changelog to find out) you need to upgrade your database schema.

4. If there have been changes in the Solr schema (check the Changelog to find out) you need to restart Jetty for the changes to take effect:

```bash
sudo service jetty restart
```

5. If you have any CKAN extensions installed from source, you may need to checkout newer versions of the extensions that work with the new CKAN version. Refer to the documentation for each extension. We recommend disabling all extensions on your ini file and re-enable them one by one to make sure they are working fine.

6. If new configuration options have been introduced (check the Changelog to find out) then check whether you need to change them from their default values. See Configuration Options for details.

3.2. Upgrading CKAN
7. Rebuild your search index by running the `ckan search-index rebuild` command:

```bash
sudo ckan search-index rebuild -r
```

See `search-index: Rebuild search index` for details of the `ckan search-index rebuild` command.

8. Finally, restart Apache and Nginx:

```bash
sudo service apache2 restart
sudo service nginx restart
```

## Upgrading a source install

**Note:** Before upgrading CKAN you should check the compatibility of any custom themes or extensions you’re using, check the changelog, and backup your database. See [Upgrading CKAN](#).

The process for upgrading a source install is the same, no matter what type of CKAN release you’re upgrading to:

1. Check the [Changelog](#) for changes regarding the required 3rd-party packages and their minimum versions (e.g. web, database and search servers) and update their installations if necessary.

2. Activate your virtualenv and switch to the ckan source directory, e.g.:

   ```bash
   . /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src/ckan
   ```

3. Checkout the new CKAN version from git, for example:

   ```bash
   git fetch
git checkout release-v2.0
   ```

   If you have any CKAN extensions installed from source, you may need to checkout newer versions of the extensions at this point as well. Refer to the documentation for each extension.

4. Update CKAN’s dependencies:

   ```bash
   pip install --upgrade -r requirements.txt
   ```

5. Register any new or updated plugins:

   ```bash
   python setup.py develop
   ```

6. If there have been changes in the Solr schema (check the [Changelog](#) to find out) you need to restart Jetty for the changes to take effect:

   ```bash
   sudo service jetty restart
   ```

7. If there have been changes in the database schema (check the [Changelog](#) to find out) you need to upgrade your database schema.

8. If new configuration options have been introduced (check the [Changelog](#) to find out) then check whether you need to change them from their default values. See [Configuration Options](#) for details.

9. Rebuild your search index by running the `ckan search-index rebuild` command:

   ```bash
   paster search-index rebuild -r --config=/etc/ckan/default/development.ini
   ```

   See `search-index: Rebuild search index` for details of the `ckan search-index rebuild` command.
10. Finally, restart your web server. For example if you have deployed CKAN using the Apache web server on Ubuntu linux, run this command:

```
sudo service apache2 reload
```

11. You’re done!

You should now be able to visit your CKAN website in your web browser and see that it’s running the new version of CKAN.

## Upgrading Postgres for the CKAN 2.6 release

CKAN 2.6 requires PostgreSQL to be of version 9.2 or later (previously it was 8.4). This is a guide to doing the upgrade if necessary.

### What are CKAN’s PostgreSQL connection settings?

Find out the PostgreSQL connection settings, as used by CKAN and Datastore:

```
grep sqlalchemy.url /etc/ckan/default/production.ini
grep ckan.datastore.write_url /etc/ckan/default/production.ini
```

where the format of the connection strings is one of these:

```
postgres://USERNAME:PASSWORD@HOST/DBNAME
postgres://USERNAME:PASSWORD@HOST:PORT/DBNAME
```

**Note:** If the ‘host’ is not configured as `localhost` then CKAN is using a PostgreSQL that is running on another machine. In this case, many of the commands below will need running on the remote machine, or if you also have PostgreSQL installed on the CKAN machine then PostgreSQL tools can usually run them on the remote host by using the `–host` parameter.

### What version are you running?

To ask PostgreSQL its version:

```
sudo -u postgres psql -c 'SHOW server_version;'
```

Or if PostgreSQL is on a remote host then you can either run the command on that machine or if you have psql installed locally you can use:

```
psql --host=HOSTNAME --username=USERNAME -W -c 'SHOW server_version;'
```

(replace `HOSTNAME` and `USERNAME` with the values from your connection settings, as previously mentioned. It will prompt you for the password).

The version will look like this:

```
server_version
----------------
9.1.9
(1 row)
```
Ignoring the last number of the three, if your PostgreSQL version number is lower than 9.2 then you should upgrade PostgreSQL before you upgrade to CKAN 2.5 or later.

**Upgrading**

**Note:** These instructions install the new PostgreSQL version alongside the existing one, so any install issues can be dealt before switching. However it is still wise to test the whole process on a test machine before upgrading for a public-facing CKAN.

**Note:** These instructions are for Ubuntu, but can be adapted to other distributions.

1. If the PostgreSQL cluster that ckan uses is not running on localhost then log-in to the PostgreSQL machine now.

2. Check to see what PostgreSQL packages are installed:

   ```
   aptitude search '~i postgres'
   ```

   These instructions assume you have been using the installed package `postgresql-9.1`. If using ckanext-spatial then you will also have PostGIS too (e.g. `postgresql-9.1-postgis`), which needs upgrading at the same time.

3. Install the Postgres Apt repository, containing newer versions. This is for Ubuntu 12.04 (Precise) - for other versions and more information, refer to: http://www.postgresql.org/download/linux/ubuntu/

   ```
   echo 'deb http://apt.postgresql.org/pub/repos/apt/ precise-pgdg main' | sudo tee /etc/apt/sources.list.d/pgdg.list
   wget --quiet -O - https://www.postgresql.org/media/keys/ACCC4CF8.asc | sudo apt-key add -
   sudo apt-get update
echo 'aptitude search postgresql-9.'
   ```

   You should now see there are packages for `postgresql-9.4` etc.

4. Install the newer PostgreSQL version. It is suggested you pick the newest stable version (from those listed in the previous step). At the time of writing, 9.5 is listed but is actually still an alpha version, so instead we’ll use 9.4:

   ```
   sudo apt-get install postgresql-9.4
   ```

   And if you need PostGIS:

   ```
   sudo apt-get install postgresql-9.4-postgis
   ```

5. If you have customized any PostgreSQL options, insert them into the new version’s config files.

   You can probably just copy the authentication rules straight:

   ```
   sudo cp /etc/postgresql/9.1/main/pg_hba.conf /etc/postgresql/9.4/main/pg_hba.conf
   ```

   And you should read through the differences in postgresql.conf. This is a handy way to do this whilst ignoring changes in the comment lines:

   ```
   diff -u -B <(grep -vE '^\s*(#|$)' /etc/postgresql/9.1/main/postgresql.conf)
   <(grep -vE '^\s*(#|$)' /etc/postgresql/9.4/main/postgresql.conf)
   ```
Once you’ve finished your changes, restart both versions of PostgreSQL:

```
sudo /etc/init.d/postgresql restart 9.4
```

6. Follow the instructions in 3. Setup a PostgreSQL database to setup PostgreSQL with a user and database. Ensure your username, password and database name match those in your connection settings (see previous section.)

7. Now log-in to the CKAN machine, if you have a separate PostgreSQL machine.

8. Activate your virtualenv and switch to the ckan source directory, e.g.:

   ```
   . /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src/ckan
   ```

9. Stop your server to prevent further writes to the database (because those changes would be lost):

   ```
sudo service apache2 stop
   ```

10. Create a back-up of the database roles:

    ```
sudo -u postgres pg_dumpall --roles-only > backup_roles.sql
    ```

    or for a remote database:

    ```
    pg_dumpall --host=HOSTNAME --username=USERNAME -W --roles-only -f backup_roles.sql
    ```

11. Make a note of the names of all the databases in your PostgreSQL so that you can create dumps of them. List them using:

    ```
sudo -u postgres psql -l
    ```

    or remotely:

    ```
    psql --host=HOSTNAME --username=USERNAME -W -l
    ```

   The databases listed should comprise:

   - CKAN database - as given in `sqlalchemy.url`. Default: ‘ckan_default’
   - Datastore database - as given in `ckan.datastore.write_url`. Default: ‘datastore_default’
   - `template0` - should not be dumped
   - `template1` - you’ll only need to dump this if you have edited it for some reason

   You may also have:

   - Test CKAN database - default ‘ckan_test’
   - Test Datastore database - default ‘datastore_test’

   which do not need to be migrated - they will be regenerated later on.

   **Warning:** If you have other databases apart from these (or have created any PostgreSQL tablespaces) then you’ll have to decide how to deal with them - they are outside the scope of this guide.

12. Create the backups of the databases you are migrating e.g.:

    ```
sudo -u postgres pg_dump -Fc -b -v ckan_default > backup_ckan.sql
sudo -u postgres pg_dump -Fc -b -v datastore_default > backup_datastore.sql
```

3.2. Upgrading CKAN
or remotely:

```bash
pg_dump --host=HOSTNAME --username=USERNAME -W ckan_default -f backup_→ckan.sql
pg_dump --host=HOSTNAME --username=USERNAME -W datastore_default -f →backup_datastore.sql
```

You need to use the `-Fc -b` options because that is required by PostGIS migration.

13. Optional: If necessary, update the PostGIS objects (known as a ‘hard upgrade’). Please refer to the documentation if you find any issues.

```bash
perl /usr/share/postgresql/9.4/contrib/postgis-2.1/postgis_restore.pl backup_ckan.˓→sql > backup_ckan_postgis.sql
```

14. Restore your PostgreSQL roles into the new PostgreSQL version cluster. If you’re not upgrading to PostgreSQL version 9.4, you’ll need to change the number in this psql command and future ones too. So:

```bash
sudo -u postgres psql --cluster 9.4/main -f backup_roles.sql
```

Expect there will be one error:

```
psql:backup_roles.sql:22: ERROR: role "postgres" already exists
```

which you can ignore - it should carry on regardless and finish ok.

15. Create the databases:

```bash
sudo -u postgres createdb --cluster 9.4/main ckan_default
sudo -u postgres createdb --cluster 9.4/main datastore_default
```

16. Optional: If necessary, enable PostGIS on the main database:

```bash
sudo -u postgres psql --cluster 9.4/main -d ckan_default -c 'ALTER TABLE ˓→geometry_columns OWNER TO ckan_default;'
sudo -u postgres psql --cluster 9.4/main -d ckan_default -c 'ALTER TABLE ˓→spatial_ref_sys OWNER TO ckan_default;'
```

To check if PostGIS was properly installed:

```bash
sudo -u postgres psql --cluster 9.4/main -d ckan_default -c "SELECT ˓→postgis_full_version()"
```

17. Now restore your databases:

```bash
sudo -u postgres psql --cluster 9.4/main -f backup_ckan.sql
sudo -u postgres psql --cluster 9.4/main -f backup_datastore.sql
```

18. Tell CKAN to use the new PostgreSQL database by switching the PostgreSQL port number in the /etc/ckan/default/production.ini. First find the correct port:

```bash
sudo pg_isclusters
```

It is likely that the old PostgreSQL is port 5432 and the new one is on 5433.

Now edit the /etc/ckan/default/production.ini to insert the port number into the sqlalchemy.url e.g.:
sqlalchemy.url = postgresql://ckan_default:pass@localhost:5433/ckan_default

And restart CKAN e.g.:

```
|restart_apache|
```

19. If you run the ckan tests then you should recreate the test databases, as described in Testing CKAN.

20. Once you are happy everything is running ok, you can delete your old PostgreSQL version’s config and database files:

```
sudo apt-get purge postgresql-9.1
```

If you also have PostGIS installed, remove that too:

```
sudo apt-get remove postgresql-9.1-postgis
```

21. Download the CKAN package for the new minor release you want to upgrade to (replace the version number with the relevant one):

```
wget http://packaging.ckan.org/python-ckan_2.5_amd64.deb
```

### 3.3 Getting started

Once you’ve finished installing CKAN, this section will walk you through getting started with your new CKAN website, including creating a CKAN sysadmin user, some test data, and the basics of configuring your CKAN site.

#### 3.3.1 Creating a sysadmin user

You have to use CKAN’s command line interface to create your first sysadmin user, and it can also be useful to create some test data from the command line. For full documentation of CKAN’s command line interface (including troubleshooting) see Command Line Interface.

**Note:** CKAN commands are executed using the `paster` command on the server that CKAN is installed on. Before running the paster commands below, you need to make sure that your virtualenv is activated and that you’re in your ckan source directory. For example:

```
. /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src/ckan
```

You have to create your first CKAN sysadmin user from the command line. For example, to create a new user called seanh and make him a sysadmin:

```
paster sysadmin add seanh email=seanh@localhost name=seanh -c /etc/ckan/default/production.ini
```

You’ll be prompted to enter a password during account creation.

Or, if you already have an existing user, you could promote him to a sysadmin:

```
paster sysadmin add seanh -c /etc/ckan/default/production.ini
```

For a list of other command line commands for managing sysadmins, run:

```
paster help sysadmin
```
3.3.2 Creating test data

It can be handy to have some test data to start with, to quickly check that everything works. You can add a standard set of test data to your site from the command line with the `create-test-data` command:

```
paster create-test-data -c /etc/ckan/default/production.ini
```

If you later want to delete this test data and start again with an empty database, you can use the `db clean` command.

For a list of other command line commands for creating tests data, run:

```
paster create-test-data --help
```

3.3.3 Config file

All of the options that can be set in the admin page and many more can be set by editing CKAN’s config file. By default, the config file is located at `/etc/ckan/default/development.ini` for development sites or `/etc/ckan/default/production.ini` for production sites. The config file can be edited in any text editor. For example, to change the title of your site you would find the `ckan.site_title` line in your config file and edit it:

```
ckan.site_title = Masaq Data Hub
```

Make sure the line is not commented-out (lines in the config file that begin with `#` are considered comments, so if there’s a `#` at the start of a line you’ve edited, delete it), save the file, and then restart your web server for the changes to take effect. For example, if using Apache on Ubuntu:

```
sudo service apache2 reload
```

For full documentation of CKAN’s config file and all the options you can set, see `Configuration Options`.

**Note:** If the same option is set in both the config file and in the admin page, the admin page setting takes precedence. You can use the `Reset` button on the admin page to clear your settings, and allow settings from the config file to take effect.

3.4 Database Management

**Note:** See `Command Line Interface` for details on running the `paster` commands mentioned below.

3.4.1 Initialization

Before you can run CKAN for the first time, you need to run `db init` to initialize your database:

```
paster db init -c /etc/ckan/default/production.ini
```

If you forget to do this you’ll see this error message in your web browser:
503 Service Unavailable: This site is currently off-line. Database is not initialised.

### 3.4.2 Cleaning

**Warning:** This will delete all data from your CKAN database!

You can delete everything in the CKAN database, including the tables, to start from scratch:

```
paster db clean -c /etc/ckan/default/production.ini
```

After cleaning the database you must do either *initialize it* or *import a previously created dump*.

### 3.4.3 Import and Export

**Dumping and Loading databases to/from a file**

PostgreSQL offers the command line tools `pg_dump` and `pg_restore` for dumping and restoring a database and its content to/from a file.

For example, first dump your CKAN database:

```
sudo -u postgres pg_dump --format=custom -d ckan_default > ckan.dump
```

**Warning:** The exported file is a complete backup of the database, and includes API keys and other user data which may be regarded as private. So keep it secure, like your database server.

**Note:** If you’ve chosen a non-default database name (i.e. not `ckan_default`) then you need to adapt the commands accordingly.

Then restore it again:

```
paster db clean -c /etc/ckan/default/production.ini
sudo -u postgres pg_restore --clean --if-exists -d ckan_default < ckan.dump
```

If you’re importing a dump from an older version of CKAN you must *upgrade the database schema* after the import.

Once the import (and a potential upgrade) is complete you should *rebuild the search index*.

**Note:** Earlier versions of CKAN offered the `paster` commands `db dump` and `db load`. These are still available but are deprecated in favor of the native tools of PostgreSQL mentioned above. `db dump` and `db load` will be removed in future versions of CKAN.

### Exporting Datasets to JSON Lines

You can export all of your CKAN site’s datasets from your database to a JSON Lines file using `ckanapi`:

```
ckanapi dump datasets -c /etc/ckan/default/production.ini -O my_datasets.jsonl
```
This is useful to create a simple public listing of the datasets, with no user information. Some simple additions to the Apache config can serve the dump files to users in a directory listing. To do this, add these lines to your virtual Apache config file (e.g. `/etc/apache2/sites-available/ckan_default.conf`):

```bash
Alias /dump/ /home/okfn/var/srvc/ckan.net/dumps/

# Disable the mod_python handler for static files
<Location /dump>
  SetHandler None
  Options +Indexes
</Location>
```

**Warning:** Don’t serve an SQL dump of your database (created using the `pg_dump` command), as those contain private user information such as email addresses and API keys.

### Exporting User Accounts to JSON Lines

You can export all of your CKAN site’s user accounts from your database to a JSON Lines file using `ckanapi`:

```bash
ckanapi dump users -c /etc/ckan/default/production.ini -O my_database_users.jsonl
```

### 3.4.4 Upgrading

**Warning:** You should *create a backup of your database* before upgrading it.

To avoid problems during the database upgrade, comment out any plugins that you have enabled in your ini file. You can uncomment them again when the upgrade finishes.

If you are upgrading to a new CKAN *major release* update your CKAN database’s schema using the `paster db upgrade` command:

```bash
paster db upgrade -c /etc/ckan/default/production.ini
```

### 3.5 Command Line Interface

Most common CKAN administration tasks can be carried out from the command line on the server that CKAN is installed on, using the `paster` command.

If you have trouble running `paster` commands, see *Troubleshooting Paster Commands* below.

**Note:** Before running a CKAN `paster` command, you have to activate your CKAN virtualenv and change to the `ckan` directory, for example:

```bash
. /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src/ckan
```

To run a `paster` command without activating the virtualenv first, you have to give the full path the `paster` script within the virtualenv, for example:
/usr/lib/ckan/default/bin/paster --plugin=ckan user list -c /etc/ckan/default/
development.ini

To run a paster command without changing to the ckan directory first, add the --plugin=ckan option to the command. For example:

paster --plugin=ckan user list -c /etc/ckan/default/development.ini

In the example commands below, we assume you’re running the commands with your virtualenv activated and from your ckan directory.

The general form of a CKAN paster command is:

paster command --config=/etc/ckan/default/development.ini

The --config option tells CKAN where to find your config file, which it reads for example to know which database it should use. As you’ll see in the examples below, this option can be given as -c for short.

command should be replaced with the name of the CKAN command that you wish to execute. Most commands have their own subcommands and options. For example, to print out a list of all of your CKAN site’s users do:

Note: You may also specify the location of your config file using the CKAN_INI environment variable. You will no longer need to use –config= or -c= to tell paster where the config file is:

export CKAN_INI=/etc/ckan/default/development.ini

paster user list -c /etc/ckan/default/development.ini

(Here user is the name of the CKAN command you’re running, and list is a subcommand of user.)

For a list of all available commands, simply run paster on its own with no command, or see Paster Commands Reference. In this case we don’t need the –c option, since we’re only asking CKAN to print out information about commands, not to actually do anything with our CKAN site:

paster

Each command has its own help text, which tells you what subcommands and options it has (if any). To print out a command’s help text, run the command with the --help option:

paster user --help

3.5.1 Troubleshooting Paster Commands

Permission Error

If you receive ‘Permission Denied’ error, try running paster with sudo.

sudo /usr/lib/ckan/default/bin/paster db clean -c /etc/ckan/default/
production.ini

Virtualenv not activated, or not in ckan dir

Most errors with paster commands can be solved by remembering to activate your virtual environment and change to the ckan directory before running the command:
Error messages such as the following are usually caused by forgetting to do this:

- **Command ‘foo’ not known** (where *foo* is the name of the command you tried to run)
- **The program ‘paster’ is currently not installed**
- **Command not found: paster**
- **ImportError: No module named fanstatic** (or other ImportErrors)

**Running paster commands provided by extensions**

If you’re trying to run a CKAN command provided by an extension that you’ve installed and you’re getting an error like **Command ‘foo’ not known** even though you’ve activated your virtualenv and changed to the ckan directory, this is because you need to run the extension’s paster commands from the extension’s source directory not CKAN’s source directory. For example:

- . /usr/lib/ckan/default/bin/activate
- cd /usr/lib/ckan/default/src/ckan
- paster foo -c /etc/ckan/default/development.ini

This should not be necessary when using the pre-installed extensions that come with CKAN.

Alternatively, you can give the extension’s name using the **--plugin** option, for example

```
paster --plugin=ckanext-foo foo -c /etc/ckan/default/development.ini
```

**Todo:** Running a paster shell with **paster --plugin=pylons shell -c ...** Useful for development?

**Wrong config file path**

**AssertionError: Config filename development.ini does not exist** This means you forgot to give the **--config** or **-c** option to tell CKAN where to find your config file. (CKAN looks for a config file named development.ini in your current working directory by default.)

**ConfigParser.MissingSectionHeaderError: File contains no section headers** This happens if the config file that you gave with the **-c** or **--config** option is badly formatted, or if you gave the wrong filename.

**IOError: [Errno 2] No such file or directory: ‘...’** This means you gave the wrong path to the **--config** or **-c** option (you gave a path to a file that doesn’t exist).

**3.5.2 Paster Commands Reference**

The following paster commands are supported by CKAN:
check-po-files: Check po files for common mistakes

Usage:

check-po-files [options] [FILE] ...

color: Create or remove a color scheme

After running this command, you’ll need to regenerate the css files. See less: Compile all root less documents into their CSS counterparts for details.

Usage:

color - creates a random color scheme
color clear - clears any color scheme
color <'HEX'> - uses as base color eg '#ff00ff' must be quoted.
color <VALUE> - a float between 0.0 and 1.0 used as base hue
color <COLOR_NAME> - html color name used for base color eg lightblue

create-test-data: Create test data

As the name suggests, this command lets you load test data when first setting up CKAN. See Creating test data for details.

dataset: Manage datasets

Usage:
### datastore: Perform commands to set up the datastore

Make sure that the datastore URLs are set properly before you run these commands.

#### Usage:

```
dataset set-permissions  # shows a SQL script to execute
```

### db: Manage databases

See [Database Management](#).

### front-end-build: Creates and minifies css and JavaScript files

#### Usage:

```
front-end-build
```

### jobs: Manage background jobs

The `jobs` command can be used to manage *Background jobs*.

New in version 2.7.

#### Run a background job worker

```
paster jobs worker [--burst] [QUEUES]
```

Starts a worker that fetches job from the *job queues* and executes them. If no queue names are given then it listens to the default queue. This is equivalent to

```
paster jobs worker default
```

If queue names are given then the worker listens to those queues and only those:

```
paster jobs worker my-custom-queue another-special-queue
```

Hence, if you want the worker to listen to the default queue and some others then you must list the default queue explicitly:

```
paster jobs worker default my-custom-queue
```
If the `--burst` option is given then the worker will exit as soon as all its queues are empty. Otherwise it will wait indefinitely until a new job is enqueued (this is the default).

---

**Note:** In a production setting you should use a more robust way of running background workers.

---

**List enqueued jobs**

```
paster jobs list [QUEUES]
```

Lists the currently enqueued jobs from the given *job queues*. If no queue names are given then the jobs from all queues are listed.

**Show details about a job**

```
paster jobs show ID
```

Shows details about the enqueued job with the given ID.

**Cancel a job**

```
paster jobs cancel ID
```

Cancels the enqueued job with the given ID. Jobs can only be canceled while they are enqueued. Once a worker has started executing a job it cannot be aborted anymore.

**Clear job queues**

```
paster jobs clear [QUEUES]
```

Cancels all jobs on the given *job queues*. If no queues are given then all queues are cleared.

**Enqueue a test job**

```
paster jobs test [QUEUES]
```

Enqueues a test job. If no *job queues* are given then the job is added to the default queue. If queue names are given then a separate test job is added to each of the queues.

**less: Compile all root less documents into their CSS counterparts**

Usage:

```
less
```
minify: Create minified versions of the given Javascript and CSS files

Usage:

paster minify [--clean] PATH

For example:

paster minify ckan/public/base
paster minify ckan/public/base/css/*.css
paster minify ckan/public/base/css/red.css

If the --clean option is provided any minified files will be removed.

notify: Send out modification notifications

Usage:

notify replay  - send out modification signals. In "replay" mode, an update signal is sent for each dataset in the database.

plugin-info: Provide info on installed plugins

As the name suggests, this commands shows you the installed plugins, their description, and which interfaces they implement

profile: Code speed profiler

Provide a ckan url and it will make the request and record how long each function call took in a file that can be read by runsnakerun.

Usage:

profile URL

The result is saved in profile.data.search. To view the profile in runsnakerun:

runsnakerun ckan.data.search.profile

You may need to install the cProfile python module.

ratings: Manage dataset ratings

Manages the ratings stored in the database, and can be used to count ratings, remove all ratings, or remove only anonymous ratings.

For example, to remove anonymous ratings from the database:

paster --plugin=ckan ratings clean-anonymous --config=/etc/ckan/std/std.ini
**rdf-export: Export datasets as RDF**

This command dumps out all currently active datasets as RDF into the specified folder:

```
paster rdf-export /path/to/store/output
```

**search-index: Rebuild search index**

Rebuilds the search index. This is useful to prevent search indexes from getting out of sync with the main database. For example:

```
paster --plugin=ckan search-index rebuild --config=/etc/ckan/std/std.ini
```

This default behaviour will clear the index and rebuild it with all datasets. If you want to rebuild it for only one dataset, you can provide a dataset name:

```
paster --plugin=ckan search-index rebuild test-dataset-name --config=/etc/ckan/std/std.ini
```

Alternatively, you can use the `-o` or `-only-missing` option to only reindex datasets which are not already indexed:

```
paster --plugin=ckan search-index rebuild -o --config=/etc/ckan/std/std.ini
```

If you don’t want to rebuild the whole index, but just refresh it, use the `-r` or `-refresh` option. This won’t clear the index before starting rebuilding it:

```
paster --plugin=ckan search-index rebuild -r --config=/etc/ckan/std/std.ini
```

There is also an option available which works like the refresh option but tries to use all processes on the computer to reindex faster:

```
paster --plugin=ckan search-index rebuild_fast --config=/etc/ckan/std/std.ini
```

There are other search related commands, mostly useful for debugging purposes:

```
search-index check - checks for datasets not indexed
search-index show DATASET_NAME - shows index of a dataset
search-index clear [DATASET_NAME] - clears the search index for the provided dataset or for the whole ckan instance
```

**sysadmin: Give sysadmin rights**

Gives sysadmin rights to a named user. This means the user can perform any action on any object. For example, to make a user called ‘admin’ into a sysadmin:

```
paster --plugin=ckan sysadmin add admin --config=/etc/ckan/std/std.ini
```

**tracking: Update tracking statistics**

Usage:
tracking update [start_date] - update tracking stats
tracking export FILE [start_date] - export tracking stats to a csv file

trans: Translation helper functions

Usage:

trans js    - generate the JavaScript translations
trans mangle - mangle the zh_TW translations for testing

Note: Since version 2.7 the JavaScript translation files are automatically regenerated if necessary when CKAN is started. Hence you usually do not need to run `paster trans js` manually.

user: Create and manage users

Lets you create, remove, list and manage users.

For example, to create a new user called ‘admin’:

```
paster --plugin=ckan user add admin --config=/etc/ckan/std/std.ini
```

To delete the ‘admin’ user:

```
paster --plugin=ckan user remove admin --config=/etc/ckan/std/std.ini
```

3.6 Organizations and authorization

Changed in version 2.0: Previous versions of CKAN used a different authorization system.

CKAN’s authorization system controls which users are allowed to carry out which actions on the site. All actions that users can carry out on a CKAN site are controlled by the authorization system. For example, the authorization system controls who can register new user accounts, delete user accounts, or create, edit and delete datasets, groups and organizations.

Authorization in CKAN can be controlled in three ways:

1. Organizations
2. Configuration file options
3. Extensions

The following sections explain each of the three methods in turn.

Note: An organization admin in CKAN is an administrator of a particular organization within the site, with control over that organization and its members and datasets. A sysadmin is an administrator of the site itself. Sysadmins can always do everything, including adding, editing and deleting datasets, organizations and groups, regardless of the organization roles and configuration options described below.
3.6.1 Organizations

Organizations are the primary way to control who can see, create and update datasets in CKAN. Each dataset can belong to a single organization, and each organization controls access to its datasets.

Datasets can be marked as public or private. Public datasets are visible to everyone. Private datasets can only be seen by logged-in users who are members of the dataset’s organization. Private datasets are not shown in general dataset searches but are shown in dataset searches within the organization.

When a user joins an organization, an organization admin gives them one of three roles: member, editor or admin.

A **member** can:

- View the organization’s private datasets.

An **editor** can do everything as **member** plus:

- Add new datasets to the organization
- Edit or delete any of the organization’s datasets
- Make datasets public or private.

An organization **admin** can do everything as **editor** plus:

- Add users to the organization, and choose whether to make the new user a member, editor or admin
- Change the role of any user in the organization, including other admin users
- Remove members, editors or other admins from the organization
- Edit the organization itself (for example: change the organization’s title, description or image)
- Delete the organization

When a user creates a new organization, they automatically become the first admin of that organization.

3.6.2 Configuration File Options

The following configuration file options can be used to customize CKAN’s authorization behavior:

**ckan.auth.anon_create_dataset**

Example:

```plaintext
ckan.auth.anon_create_dataset = False
```

Default value: **False**

Allow users to create datasets without registering and logging in.

**ckan.auth.create_unowned_dataset**

Example:

```plaintext
ckan.auth.create_unowned_dataset = False
```

Default value: **True**

Allow the creation of datasets not owned by any organization.
ckan.auth.create_dataset_if_not_in_organization

Example:

ckan.auth.create_dataset_if_not_in_organization = False

Default value: True

Allow users who are not members of any organization to create datasets, default: true. create_unowned_dataset must also be True, otherwise setting create_dataset_if_not_in_organization to True is meaningless.

ckan.auth.user_create_groups

Example:

ckan.auth.user_create_groups = True

Default value: False

Allow users to create groups.

ckan.auth.user_create_organizations

Example:

ckan.auth.user_create_organizations = False

Default value: True

Allow users to create organizations.

ckan.auth.user_delete_groups

Example:

ckan.auth.user_delete_groups = False

Default value: True

Allow users to delete groups.

ckan.auth.user_delete_organizations

Example:

ckan.auth.user_delete_organizations = False

Default value: True

Allow users to delete organizations.
**ckan.auth.create_user_via_api**

Example:

```python
ckan.auth.create_user_via_api = False
```

Default value: False

Allow new user accounts to be created via the API by anyone. When False only sysadmins are authorised.

**ckan.auth.create_user_via_web**

Example:

```python
ckan.auth.create_user_via_web = True
```

Default value: True

Allow new user accounts to be created via the Web.

**ckan.auth.roles_that_cascade_to_sub_groups**

Example:

```python
ckan.auth.roles_that_cascade_to_sub_groups = admin editor
```

Default value: admin

Makes role permissions apply to all the groups down the hierarchy from the groups that the role is applied to.

E.g. a particular user has the ‘admin’ role for group ‘Department of Health’. If you set the value of this option to ‘admin’ then the user will automatically have the same admin permissions for the child groups of ‘Department of Health’ such as ‘Cancer Research’ (and its children too and so on).

**ckan.auth.public_user_details**

Example:

```python
ckan.auth.public_user_details = False
```

Default value: True

 Restricts anonymous access to user information. If is set to False accessing users details when not logged in will raise a Not Authorized exception.

**Note:** This setting should be used when user registration is disabled (ckan.auth.create_user_via_web = False), otherwise users can just create an account to see other users details.

### 3.6.3 Extensions

CKAN extensions can implement custom authorization rules by overriding the authorization functions that CKAN uses. This is done by implementing the IAuthFunctions plugin interface.
Dataset visibility is determined by permission labels stored in the search index. Implement the IPermissionLabels plugin interface then rebuild your search index to change your dataset visibility rules. There is no need to override the package_show auth function, it will inherit these changes automatically.

To get started with writing CKAN extensions, see Extending guide.

### 3.7 Data preview and visualization

Changed in version 2.3: The whole way resource previews are handled was changed on CKAN 2.3. Please refer to previous versions of the documentation if you are using an older CKAN version.

#### 3.7.1 Overview

The CKAN resource page can contain one or more visualizations of the resource data or file contents (a table, a bar chart, a map, etc). These are commonly referred to as resource views.
The main features of resource views are:

- One resource can have multiple views of the same data (for example a grid and some graphs for tabular data).
- Dataset editors can choose which views to show, reorder them and configure them individually.
- Individual views can be embedded on external sites.

Different view types are implemented via custom plugins, which can be activated on a particular CKAN site. Once these plugins are added, instance administrators can decide which views should be created by default if the resource is suitable (for instance a table on resources uploaded to the DataStore, a map for spatial data, etc.).

Whether a particular resource can be rendered by the different view plugins is decided by the view plugins themselves. This is generally done checking the resource format or whether its data is on the DataStore extension or not.
3.7.2 Managing resource views

Users who are allowed to edit a particular dataset can also manage the views for its resources. To access the management interface, click on the Manage button on the resource page and then on the Views tab. From here you can create new views, update or delete existing ones and reorder them.

The New view dropdown will show the available view types for this particular resource. If the list is empty, you may need to add the relevant view plugins to the ckan.plugins setting on your configuration file, eg:

```
ckan.plugins = ... image_view recline_view pdf_view
```

3.7.3 Defining views to appear by default

From the management interface you can create and edit views manually, but in most cases you will want views to be created automatically on certain resource types, so data can be visualized straight away after uploading or linking to a file.

To do so, you define a set of view plugins that should be checked whenever a dataset or resource is created or updated. For each of them, if the resource is a suitable one, a view will be created.

This is configured with the ckan.views.default_views setting. In it you define the view plugins that you want to be created as default:

```
ckan.views.default_views = recline_view pdf_view geojson_view
```

This configuration does not mean that each new resource will get all of these views by default, but that for instance if the uploaded file is a PDF file, a PDF viewer will be created automatically and so on.

3.7.4 Available view plugins

Some view plugins for common formats are included in the main CKAN repository. These don’t require further setup and can be directly added to the ckan.plugins setting.
Data Explorer

View plugin: recline_view

Adds a rich widget, based on the Recline Javascript library. It allows querying, filtering, graphing and mapping data. The Data Explorer is optimized for displaying structured data hosted on the DataStore extension.

The Data Explorer can also display certain formats of tabular data (CSV and Excel files) without its contents being uploaded to the DataStore. This is done via the DataProxy, an external service that will parse the contents of the file and return a response that the view widget understands. However, as the resource must be downloaded by the DataProxy service and parsed before it is viewed, this option is slower and less reliable than viewing data that is in the DataStore. It also does not properly support different encodings, proper field type detection, etc so users are strongly encouraged to host data on the DataStore instead.

**Note:** Support for the DataProxy will be dropped on future CKAN releases

The three main panes of the Data Explorer are also available as separate views.
DataStore Grid

View plugin: recline_grid_view

Displays a filterable, sortable, table view of structured data.

This plugin requires data to be in the DataStore.
**DataStore Graph**

View plugin: `recline_graph_view`

Allows to create graphs from data stored on the DataStore. You can choose the graph type (such as lines, bars, columns, etc) and restrict the displayed data, by filtering by a certain field value or defining an offset and the number of rows.

This plugin requires data to be in the DataStore.
DataStore Map

View plugin: recline_map_view

Shows data stored on the DataStore in an interactive map. It supports plotting markers from a pair of latitude / longitude fields or from a field containing a GeoJSON representation of the geometries. The configuration also allows to cluster markers if there is a high density of them and to zoom automatically to the rendered features.

This plugin requires data to be in the DataStore.

There is partial support to change the map tiles to a different service, such as Mapbox. Look below for an example to add to your configuration file:

```bash
#Mapbox example:
ckanext.spatial.common_map.type = mapbox
ckanext.spatial.common_map.mapbox.map_id = <id>
ckanext.spatial.common_map.mapbox.access_token = <token>
ckanext.spatial.common_map.mapbox.mapbox_attribution = © <a target=_blank href='https://www.mapbox.com/map-feedback/'>Mapbox</a> © <a target=_blank href='http://www.openstreetmap.org/copyright'>OpenStreetMap</a>
ckanext.spatial.common_map.mapbox.subdomains = <subdomains>

#Custom example:
ckanext.spatial.common_map.type = custom
ckanext.spatial.common_map.custom.url = <url>
ckanext.spatial.common_map.custom.tms = <tms>
ckanext.spatial.common_map.custom.attribute = <copyright link>
ckanext.spatial.common_map.subdomains = <subdomains>
```
View plugin: text_view

Displays files in XML, JSON or plain text based formats with the syntax highlighted. The formats detected can be configured using the ckan.preview.xml_formats, ckan.preview.json_formats and ckan.preview.text_formats configuration options respectively.

If you want to display files that are hosted in a different server from your CKAN instance (eg that haven’t been uploaded to CKAN) you will need to enable the Resource Proxy plugin.
View plugin: `image_view`

If the resource format is a common image format like PNG, JPEG or GIF, it adds an `<img>` tag pointing to the resource URL. You can provide an alternative URL on the edit view form. The available formats can be configured using the `ckan.preview.image_formats` configuration option.
Web page view

View plugin: webpage_view

Adds an `<iframe>` tag to embed the resource URL. You can provide an alternative URL on the edit view form.

**Warning:** Do not activate this plugin unless you trust the URL sources. It is not recommended to enable this view type on instances where all users can create datasets.

Other view plugins

There are many more view plugins developed by the CKAN team and others which are hosted on separate repositories. Some examples include:

- **Dashboard**: Allows to combine multiple views into a single dashboard.
- **PDF viewer**: Allows to render PDF files on the resource page.
- **GeoJSON map**: Renders GeoJSON files on an interactive map.
- **Choropleth map**: Displays data on the DataStore on a choropleth map.
- **Basic charts**: Provides alternative graph types and renderings.

If you want to add another view type to this list, edit this file by sending a pull request on GitHub.

New plugins to render custom view types can be implemented using the `IResourceView` interface.

3.7. Data preview and visualization 79
Todo: Link to a proper tutorial for writing custom views

3.7.5 Resource Proxy

As resource views are rendered on the browser, if the file they are accessing is located in a different domain than the one CKAN is hosted, the browser will block access to it because of the same-origin policy. For instance, files hosted on www.example.com won’t be able to be accessed from the browser if CKAN is hosted on data.catalog.com.

To allow view plugins access to external files you need to activate the resource_proxy plugin on your configuration file:

```bash
ckan.plugins = resource_proxy ...
```

This will request the file on the server side and serve it from the same domain as CKAN.

You can modify the maximum allowed size for proxied files using the `ckan.resource_proxy.max_file_size` configuration setting.

3.7.6 Migrating from previous CKAN versions

If you are upgrading an existing instance running CKAN version 2.2.x or lower to CKAN 2.3 or higher, you need to perform a migration process in order for the resource views to appear. If the migration does not take place, resource views will only appear when creating or updating datasets or resources, but not on existing ones.

The migration process involves creating the necessary view objects in the database, which can be done using the `paster views create` command.

**Note:** The `paster views create` command uses the search API to get all necessary datasets and resources, so make sure your search index is up to date before starting the migration process.

The way the `paster views create` command works is getting all or a subset of the instance datasets from the search index, and for each of them checking against a list of view plugins if it is necessary to create a view object. This gets determined by each of the individual view plugins depending on the dataset’s resources fields.

Before each run, you will be prompted with the number of datasets affected and asked if you want to continue (unless you pass the `-y` option):

```bash
You are about to check 3336 datasets for the following view plugins: ['image_view', 'recline_view', 'text_view']
Do you want to continue? [Y/n]
```

**Note:** On large CKAN instances the migration process can take a significant time if using the default options. It is worth planning in advance and split the process using the search parameters to only check relevant datasets. The following documentation provides guidance on how to do this.

If no view types are provided, the default ones are used (check Defining views to appear by default to see how these are defined):

```bash
paster views create
```

Specific view types can be also provided:
For certain view types (the ones with plugins included in the main CKAN core), default filters are applied to the search to only get relevant resources. For instance if `image_view` is defined, filters are added to the search to only get datasets with resources that have image formats (png, jpg, etc).

You can also provide arbitrary search parameters like the ones supported by `package_search()`. This can be useful for instance to only include datasets with resources of a certain format:

```
paster views create geojson_view -s '{"fq": "res_format:GEOJSON"}"
```

To instead avoid certain formats you can do:

```
paster views create -s '{"fq": "-res_format:HTML"}"
```

Of course this is not limited to resource formats, you can filter out or in using any field, as in a normal dataset search:

```
paster views create -s '{"q": "groups:visualization-examples"}"
```

Tip: If you set the `ckan_logger` level to `DEBUG` on your configuration file you can see the full search parameters being sent to Solr.

For convenience, there is also an option to create views on a particular dataset or datasets:

```
paster views create -d dataset_id
```

```
paster views create -d dataset_name -d dataset_name
```

### 3.7.7 Command line interface

The `paster views` command allows to create and remove resource views objects from the database in bulk.

Check the command help for the full options:

```
paster views create -h
```

Todo: Tutorial for writing custom view types.

### 3.8 FileStore and file uploads

When enabled, CKAN’s FileStore allows users to upload data files to CKAN resources, and to upload logo images for groups and organizations. Users will see an upload button when creating or updating a resource, group or organization.

New in version 2.2: Uploading logo images for groups and organizations was added in CKAN 2.2.

Changed in version 2.2: Previous versions of CKAN used to allow uploads to remote cloud hosting but we have simplified this to only allow local file uploads (see Migration from 2.1 to 2.2 for details on how to migrate). This is to give CKAN more control over the files and make access control possible.

See also:

*DataStore extension*
Resource files linked-to from CKAN or uploaded to CKAN’s FileStore can also be pushed into CKAN’s DataStore, which then enables data previews and a data API for the resources.

### 3.8.1 Setup file uploads

To setup CKAN’s FileStore with local file storage:

1. Create the directory where CKAN will store uploaded files:
   
   ```bash
   sudo mkdir -p /var/lib/ckan/default
   ```

2. Add the following line to your CKAN config file, after the `[app:main]` line:
   
   ```
   ckan.storage_path = /var/lib/ckan/default
   ```

3. Set the permissions of your `ckan.storage_path` directory. For example if you’re running CKAN with Apache, then Apache’s user (`www-data` on Ubuntu) must have read, write and execute permissions for the `ckan.storage_path`:
   
   ```bash
   sudo chown www-data /var/lib/ckan/default
   sudo chmod u+rwx /var/lib/ckan/default
   ```

4. Restart your web server, for example to restart Apache:
   
   ```bash
   sudo service apache2 reload
   ```

### 3.8.2 FileStore API

Changed in version 2.2: The FileStore API was redesigned for CKAN 2.2. The previous API has been deprecated.

Files can be uploaded to the FileStore using the `resource_create()` and `resource_update()` action API functions. You can post multipart/form-data to the API and the key, value pairs will treated as as if they are a JSON object. The extra key `upload` is used to actually post the binary data.

For example, to create a new CKAN resource and upload a file to it using curl:

```
curl -H 'Authorization: your-api-key' 'http://yourhost/api/action/resource_create' --
   → form upload=@filetoupload --form package_id=my_dataset
```

(Curl automatically sends a multipart-form-data heading with you use the --form option.)

To create a new resource and upload a file to it using the Python library `requests`:

```python
import requests
requests.post('http://0.0.0.0:5000/api/action/resource_create',
   data={"package_id":"my_dataset"},
   headers={'X-CKAN-API-Key": "21a47217-6d7b-49c5-88f9-72ebd5a4d4bb"'},
   files=[('upload', file('/path/to/file/to/upload.csv'))])
```

(Requests automatically sends a multipart-form-data heading when you use the files= parameter.)

To overwrite an uploaded file with a new version of the file, post to the `resource_update()` action and use the upload field:

```
curl -H 'Authorization: your-api-key' 'http://yourhost/api/action/resource_update' --
   → form upload=@newfiletoupload --form id=resourceid
```

To replace an uploaded file with a link to a file at a remote URL, use the `clear_upload` field:
3.8.3 Migration from 2.1 to 2.2

If you are using pairtree local file storage then you can keep your current settings without issue. The pairtree and new storage can live side by side but you are still encouraged to migrate. If you change your config options to the ones specified in this docs you will need to run the migration below.

If you are running remote storage then all previous links will still be accessible but if you want to move the remote storage documents to the local storage you will run the migration also.

In order to migrate make sure your CKAN instance is running as the script will request the data from the instance using APIs. You need to run the following on the command line to do the migration:

```
paster db migrate-filestore
```

This may take a long time especially if you have a lot of files remotely. If the remote hosting goes down or the job is interrupted it is save to run it again and it will try all the unsuccessful ones again.

3.8.4 Custom Internet media types (MIME types)

New in version 2.2.

CKAN uses the default Python library `mimetypes` to detect the media type of an uploaded file. If some particular format is not included in the ones guessed by the `mimetypes` library, a default `application/octet-stream` value will be returned.

Users can still register a more appropriate media type by using the `mimetypes` library. A good way to do so is to use the `IConfigurer` interface so the custom types get registered on startup:

```
import mimetypes
import ckan.plugins as p

class MyPlugin(p.SingletonPlugin):
    p.implements(p.IConfigurer)
    def update_config(self, config):
        mimetypes.add_type('application/json', '.geojson')
        # ...
```

3.9 DataStore extension

The CKAN DataStore extension provides an *ad hoc* database for storage of structured data from CKAN resources. Data can be pulled out of resource files and stored in the DataStore.

When a resource is added to the DataStore, you get:

- Automatic data previews on the resource’s page, using the *Data Explorer extension*
- *The DataStore API*: search, filter and update the data, without having to download and upload the entire data file.

The DataStore is integrated into the *CKAN API* and authorization system.

The DataStore is generally used alongside the *DataPusher*, which will automatically upload data to the DataStore from suitable files, whether uploaded to CKAN’s FileStore or externally linked.

### 3.9.1 Relationship to FileStore

The DataStore is distinct but complementary to the FileStore (see *FileStore and file uploads*). In contrast to the FileStore which provides ‘blob’ storage of whole files with no way to access or query parts of that file, the DataStore is like a database in which individual data elements are accessible and queryable. To illustrate this distinction, consider storing a spreadsheet file like a CSV or Excel document. In the FileStore this file would be stored directly. To access it you would download the file as a whole. By contrast, if the spreadsheet data is stored in the DataStore, one would be able to access individual spreadsheet rows via a simple web API, as well as being able to make queries over the spreadsheet contents.

### 3.9.2 Setting up the DataStore

#### Note:

The DataStore (like CKAN) requires PostgreSQL 9.2 or later. This was released in 2012, is widely available. At the time of writing, the only version that is not supported by CKAN that has not been made ‘end-of-life’ by the PostgreSQL community is 9.1.

Changed in version 2.6: Previous CKAN (and DataStore) versions were compatible with earlier versions of PostgreSQL.

#### 1. Enable the plugin

Add the `datastore` plugin to your CKAN config file:

```
ckan.plugins = datastore
```
2. Set-up the database

**Warning:** Make sure that you follow the steps in *Set Permissions* below correctly. Wrong settings could lead to serious security issues.

The DataStore requires a separate PostgreSQL database to save the DataStore resources to.

List existing databases:

```
sudo -u postgres psql -l
```

Check that the encoding of databases is UTF8, if not internationalisation may be a problem. Since changing the encoding of PostgreSQL may mean deleting existing databases, it is suggested that this is fixed before continuing with the datastore setup.

**Create users and databases**

**Tip:** If your CKAN database and DataStore databases are on different servers, then you need to create a new database user on the server where the DataStore database will be created. As in *Installing CKAN from source* we’ll name the database user ckan_default:

```
sudo -u postgres createuser -S -D -R -P -l ckan_default
```

Create a database_user called datastore_default. This user will be given read-only access to your DataStore database in the *Set Permissions* step below:

```
sudo -u postgres createuser -S -D -R -P -l datastore_default
```

Create the database (owned by ckan_default), which we’ll call datastore_default:

```
sudo -u postgres createdb -O ckan_default datastore_default -E utf-8
```

**Set URLs**

Now, uncomment the `ckan.datastore.write_url` and `ckan.datastore.read_url` lines in your CKAN config file and edit them if necessary, for example:

```
ckan.datastore.write_url = postgresql://ckan_default:pass@localhost/datastore_default
ckan.datastore.read_url = postgresql://datastore_default:pass@localhost/datastore_default
```

Replace *pass* with the passwords you created for your ckan_default and datastore_default database users.

**Set permissions**

Once the DataStore database and the users are created, the permissions on the DataStore and CKAN database have to be set. CKAN provides a paster command to help you correctly set these permissions.

If you are able to use the *psql* command to connect to your database as a superuser, you can use the *datastore set-permissions* command to emit the appropriate SQL to set the permissions.
For example, if you can connect to your database server as the `postgres` superuser using:

```
sudo -u postgres psql
```

Then you can use this connection to set the permissions:

```
sudo ckan datastore set-permissions | sudo -u postgres psql --set ON_ERROR_STOP=1
```

**Note:** If you performed a source install, you will need to replace all references to `sudo ckan ...` with `paster --plugin=ckan ...` and provide the path to the config file, e.g. `
```
paster --plugin=ckan datastore set-permissions -c /etc/ckan/default/development.ini | sudo -u postgres psql --set ON_ERROR_STOP=1
```

If your database server is not local, but you can access it over SSH, you can pipe the permissions script over SSH:

```
sudo ckan datastore set-permissions |
ssh dbserver sudo -u postgres psql --set ON_ERROR_STOP=1
```

If you can’t use the `psql` command in this way, you can simply copy and paste the output of:

```
sudo ckan datastore set-permissions
```

into a PostgreSQL superuser console.

### 3. Test the set-up

The DataStore is now set-up. To test the set-up, (re)start CKAN and run the following command to list all DataStore resources:

```
curl -X GET "http://127.0.0.1:5000/api/3/action/datastore_search?resource_id=_table_˓→metadata"
```

This should return a JSON page without errors.

To test the whether the set-up allows writing, you can create a new DataStore resource. To do so, run the following command:

```
curl -X POST http://127.0.0.1:5000/api/3/action/datastore_create -H "Authorization: →{YOUR-API-KEY}" -d '{"resource": {"package_id": "{PACKAGE-ID}"}, "fields": [ {"id": ...
```

Replace `{YOUR-API-KEY}` with a valid API key and `{PACKAGE-ID}` with the id of an existing CKAN dataset.

A table named after the resource id should have been created on your DataStore database. Visiting this URL should return a response from the DataStore with the records inserted above:

```
http://127.0.0.1:5000/api/3/action/datastore_search?resource_id={RESOURCE_ID}
```

Replace `{RESOURCE-ID}` with the resource id that was returned as part of the response of the previous API call.

You can now delete the DataStore table with:

```
```

To find out more about the DataStore API, see *The DataStore API*. 

---

86 Chapter 3. Maintainer’s guide
3.9.3 DataPusher: Automatically Add Data to the DataStore

Often, one wants data that is added to CKAN (whether it is linked to or uploaded to the FileStore) to be automatically added to the DataStore. This requires some processing, to extract the data from your files and to add it to the DataStore in the format the DataStore can handle.

This task of automatically parsing and then adding data to the DataStore is performed by the DataPusher, a service that runs asynchronously and can be installed alongside CKAN.

To install this please look at the docs here: http://docs.ckan.org/projects/datapusher

Note: The DataPusher only imports the first worksheet of a spreadsheet. It also does not support duplicate column headers. That includes blank column headings.

3.9.4 Data Dictionary

DataStore columns may be described with a Data Dictionary. A Data Dictionary tab will appear when editing any resource with a DataStore table. The Data Dictionary form allows entering the following values for each column:

• Type Override: the type to be used the next time DataPusher is run to load data into this column
• Label: a human-friendly label for this column
• Description: a full description for this column in markdown format

Extension developers may add new fields to this form by overriding the default Data Dictionary form template datastore/snippets/dictionary_form.html.

The Data Dictionary is set through the API as part of the Fields passed to datastore_create() and returned from datastore_search().

3.9.5 Downloading Resources

A DataStore resource can be downloaded in the CSV file format from {CKAN-URL}/datastore/dump/{RESOURCE-ID}.

For an Excel-compatible CSV file use {CKAN-URL}/datastore/dump/{RESOURCE-ID}?bom=true.

Other formats supported include tab-separated values (?format=tsv), JSON (?format=json) and XML (?format=xml). E.g. to download an Excel-compatible tab-separated file use {CKAN-URL}/datastore/dump/{RESOURCE-ID}?format=tsv&bom=true.

3.9.6 The DataStore API

The CKAN DataStore offers an API for reading, searching and filtering data without the need to download the entire file first. The DataStore is an ad hoc database which means that it is a collection of tables with unknown relationships. This allows you to search in one DataStore resource (a table in the database) as well as queries across DataStore resources.

Data can be written incrementally to the DataStore through the API. New data can be inserted, existing data can be updated or deleted. You can also add a new column to an existing table even if the DataStore resource already contains some data.

Triggers may be added to enforce validation, clean data as it is loaded or even record record histories. Triggers are PL/pgSQL functions that must be created by a sysadmin.
You will notice that we tried to keep the layer between the underlying PostgreSQL database and the API as thin as possible to allow you to use the features you would expect from a powerful database management system.

A DataStore resource cannot be created on its own. It is always required to have an associated CKAN resource. If data is stored in the DataStore, it will automatically be previewed by the `recline preview extension`.

### Making a DataStore API request

Making a DataStore API request is the same as making an Action API request: you post a JSON dictionary in an HTTP POST request to an API URL, and the API also returns its response in a JSON dictionary. See the [API guide](#) for details.

### API reference

**Note:** Lists can always be expressed in different ways. It is possible to use lists, comma separated strings or single items. These are valid lists: `['foo', 'bar'], 'foo, bar', "foo", "bar" and 'foo'.` Additionally, there are several ways to define a boolean value. `True, on` and `1` are all valid boolean values.

**Note:** The table structure of the DataStore is explained in [Internal structure of the database](#).

ckanext.datastore.logic.action.datastore_create(context, data_dict)

Adds a new table to the DataStore.

The datastore_create action allows you to post JSON data to be stored against a resource. This endpoint also supports altering tables, aliases and indexes and bulk insertion. This endpoint can be called multiple times to initially insert more data, add fields, change the aliases or indexes as well as the primary keys.

To create an empty datastore resource and a CKAN resource at the same time, provide `resource` with a valid `package_id` and omit the `resource_id`.

If you want to create a datastore resource from the content of a file, provide `resource` with a valid `url`.

See [Fields](#) and [Records](#) for details on how to lay out records.

**Parameters**

- **resource_id**(string) – resource id that the data is going to be stored against.

- **force**(bool (optional, default: False)) – set to True to edit a read-only resource

- **resource**(dictionary) – resource dictionary that is passed to `resource_create()`. Use instead of `resource_id` (optional)

- **aliases**(list or comma separated string) – names for read only aliases of the resource. (optional)

- **fields**(list of dictionaries) – fields/columns and their extra metadata. (optional)

- **records**(list of dictionaries) – the data, eg: `["dob": "2005", "some_stuff": ["a", "b"]]` (optional)

- **primary_key**(list or comma separated string) – fields that represent a unique key (optional)

- **indexes**(list or comma separated string) – indexes on table (optional)
**triggers** *(list of dictionaries)* – trigger functions to apply to this table on update/insert. Functions may be created with `datastore_function_create()`. Eg: 

```json
[ {
    "function": "trigger_clean_reference"
  },
  {
    "function": "trigger_check_codes"
  }
]
```

Please note that setting the aliases, indexes or primary_key replaces the existing aliases or constraints. Setting records appends the provided records to the resource.

**Results:**

- **Returns**  The newly created data object, excluding records passed.
- **Return type** dictionary

See **Fields** and **Records** for details on how to lay out records.

```python
datastore_run_triggers(context, data_dict)
datastore_upsert(context, data_dict)
datastore_info(context, data_dict)
```

**Parameters**

- **resource_id**(string) – resource id that the data is going to be stored under.
- **force**(bool (optional, default: False)) – set to True to edit a read-only resource
- **records** *(list of dictionaries)* – the data, eg: `[{"dob": "2005", "some_stuff": ["a","b"]}]` (optional)
- **method**(string) – the method to use to put the data into the datastore. Possible options are: upsert, insert, update (optional, default: upsert)

**Results:**

- **Returns**  The modified data object.
- **Return type** dictionary

**3.9. DataStore extension**
Parameters **id** *(A UUID)* – Id of the resource we want info about

`ckanext.datastore.logic.action.datastore_delete(context, data_dict)`

Deletes a table or a set of records from the DataStore.

**Parameters**

- **resource_id**(string) – resource id that the data will be deleted from. (optional)
- **force**(bool (optional, default: False)) – set to True to edit a read-only resource
- **filters**(dictionary) – filters to apply before deleting (eg {“name”: “fred”}). If missing delete whole table and all dependent views. (optional)

**Results:**

**Returns** Original filters sent.

**Return type** dictionary

`ckanext.datastore.logic.action.datastore_search(context, data_dict)`

Search a DataStore resource.

The datastore_search action allows you to search data in a resource. DataStore resources that belong to private CKAN resource can only be read by you if you have access to the CKAN resource and send the appropriate authorization.

**Parameters**

- **resource_id**(string) – id or alias of the resource to be searched against
- **filters**(dictionary) – matching conditions to select, e.g {“key1”: “a”, “key2”: “b”} (optional)
- **q**(string or dictionary) – full text query. If it’s a string, it’ll search on all fields on each row. If it’s a dictionary as {“key1”: “a”, “key2”: “b”}, it’ll search on each specific field (optional)
- **distinct**(bool) – return only distinct rows (optional, default: false)
- **plain**(bool) – treat as plain text query (optional, default: true)
- **language**(string) – language of the full text query (optional, default: english)
- **limit**(int) – maximum number of rows to return (optional, default: 100)
- **offset**(int) – offset this number of rows (optional)
- **fields**(list or comma separated string) – fields to return (optional, default: all fields in original order)
- **sort**(string) – comma separated field names with ordering e.g.: “fieldname1, fieldname2 desc”
- **include_total**(bool) – True to return total matching record count (optional, default: true)
- **records_format**(controlled list) – the format for the records return value: ‘objects’ (default) list of {fieldname1: value1, . . . } dicts, ‘lists’ list of [value1, value2, . . . ] lists, ‘csv’ string containing comma-separated values with no header, ‘tsv’ string containing tab-separated values with no header

Setting the **plain** flag to false enables the entire PostgreSQL full text search query language.

A listing of all available resources can be found at the alias _table_metadata_.

90 Chapter 3. Maintainer’s guide
If you need to download the full resource, read *Downloading Resources*.

**Results:**

The result of this action is a dictionary with the following keys:

**Return type** A dictionary with the following keys

**Parameters**

- `fields` (*list of dictionaries*) – fields/columns and their extra metadata
- `offset` (*int*) – query offset value
- `limit` (*int*) – query limit value
- `filters` (*list of dictionaries*) – query filters
- `total` (*int*) – number of total matching records
- `records` (*depends on records_format value passed*) – list of matching results

```python
ckanext.datastore.logic.action.datastore_search_sql(context, data_dict)
```

Execute SQL queries on the DataStore.

The `datastore_search_sql` action allows a user to search data in a resource or connect multiple resources with join expressions. The underlying SQL engine is the PostgreSQL engine. There is an enforced timeout on SQL queries to avoid an unintended DOS. Queries are only allowed if you have access to the all the CKAN resources in the query and send the appropriate authorization.

**Note:** This action is not available when `ckan.datastore.sqlsearch.enabled` is set to false

**Note:** When source data columns (i.e. CSV) heading names are provided in all UPPERCASE you need to double quote them in the SQL select statement to avoid returning null results.

**Parameters**

- `sql` (*string*) – a single SQL select statement

**Results:**

The result of this action is a dictionary with the following keys:

**Return type** A dictionary with the following keys

**Parameters**

- `fields` (*list of dictionaries*) – fields/columns and their extra metadata
- `records` (*list of dictionaries*) – list of matching results

```python
ckanext.datastore.logic.action.set_datastore_active_flag(model, data_dict, flag)
```

Set appropriate datastore_active flag on CKAN resource.

Called after creation or deletion of DataStore table.

```python
ckanext.datastore.logic.action.datastore_function_create(context, data_dict)
```

Create a trigger function for use with datastore_create

**Parameters**

- `name` (*string*) – function name
• `or_replace (bool)` – True to replace if function already exists (default: False)
• `rettype (string)` – set to ‘trigger’ (only trigger functions may be created at this time)
• `definition (string)` – PL/pgSQL function body for trigger function

`ckanext.datastore.logic.action.datastore_function_delete (context, data_dict)`
Delete a trigger function

**Parameters**
- `name (string)` – function name

**Fields**

Fields define the column names and the type of the data in a column. A field is defined as follows:

```json
{
    "id": # the column name (required)
    "type": # the data type for the column
    "info": {
        "label": # human-readable label for column
        "notes": # markdown description of column
        "type_override": # type for datapusher to use when importing data
        ...: # other user-defined fields
    }
}
```

Field types not provided will be guessed based on the first row of provided data. Set the types to ensure that future inserts will not fail because of an incorrectly guessed type. See Field types for details on which types are valid.

Extra "info" field values will be stored along with the column. "label", "notes" and "type_override" can be managed from the default Data Dictionary form. Additional fields can be stored by customizing the Data Dictionary form or by passing their values to the API directly.

**Example:**

```json
[
    {
        "id": "code_number",
        "type": "numeric"
    },
    {
        "id": "description",
        "type": "text",
        "info": {
            "label": "Description",
            "notes": "A brief usage description for this code",
            "example": "Used for temporary service interruptions"
        }
    }
]
```

**Records**

A record is the data to be inserted in a DataStore resource and is defined as follows:
{  
  column_1_id: value_1,
  column_2_id: value_2,
  ...
}

Example:

[
  {
    "code_number": 10,
    "description": "Submitted successfully"
  },
  {
    "code_number": 42,
    "description": "In progress"
  }
]

Field types

The DataStore supports all types supported by PostgreSQL as well as a few additions. A list of the PostgreSQL types can be found in the type section of the documentation. Below you can find a list of the most common data types. The json type has been added as a storage for nested data.

In addition to the listed types below, you can also use array types. They are defines by prepending a _ or appending [[] or [n] where n denotes the length of the array. An arbitrarily long array of integers would be defined as int[].

text Arbitrary text data, e.g. Here’s some text.

json Arbitrary nested json data, e.g {"foo": 42, "bar": [1, 2, 3]}. Please note that this type is a custom type that is wrapped by the DataStore.

date Date without time, e.g 2012-5-25.

time Time without date, e.g 12:42.

timestamp Date and time, e.g 2012-10-01T02:43Z.

int Integer numbers, e.g 42, 7.

float Floats, e.g. 1.61803.

bool Boolean values, e.g. true, 0

You can find more information about the formatting of dates in the date/time types section of the PostgreSQL documentation.

Resource aliases

A resource in the DataStore can have multiple aliases that are easier to remember than the resource id. Aliases can be created and edited with the datastore_create() API endpoint. All aliases can be found in a special view called _table_metadata. See Internal structure of the database for full reference.
HTSQL support

The ckanext-htsql extension adds an API action that allows a user to search data in a resource using the HTSQL query expression language. Please refer to the extension documentation to know more.

Comparison of different querying methods

The DataStore supports querying with multiple API endpoints. They are similar but support different features. The following list gives an overview of the different methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Ease of use</th>
<th>Flexibility</th>
<th>Query language</th>
<th>Join resources</th>
<th>Internal structure of the database</th>
</tr>
</thead>
<tbody>
<tr>
<td>datastore_search()</td>
<td>Easy</td>
<td>Low</td>
<td>Custom (JSON)</td>
<td>No</td>
<td>The DataStore is a thin layer on top of a PostgreSQL database. Each DataStore resource belongs to a CKAN resource. The name of a table in the DataStore is always the resource id of the CKAN resource for the data. As explained in Resource aliases, a resource can have mnemonic aliases which are stored as views in the database. All aliases (views) and resources (tables respectively relations) of the DataStore can be found in a special view called _table_metadata. To access the list, open http://{YOUR-CKAN-INSTALLATION}/api/3/action/datastore_search?resource_id=_table_metadata. _table_metadata has the following fields: _id Unique key of the relation in _table_metadata. alias_of Name of a relation that this alias point to. This field is null iff the name is not an alias. name Contains the name of the alias if alias_of is not null. Otherwise, this is the resource id of the CKAN resource for the DataStore resource. oid The PostgreSQL object ID of the table that belongs to name.</td>
</tr>

<td>No</td>
<td></td>
</tr>
</tbody>
</table>

Internal structure of the database

3.9.7 Extending DataStore

Starting from CKAN version 2.7, backend used in DataStore can be replaced with custom one. For this purpose, custom extension must implement ckanext.datastore.interfaces.IDatastoreBackend, which provides one method - register_backends. It should return dictionary with names of custom backends as keys and classes, that represent those backends as values. Each class supposed to be inherited from ckanext.datastore.backend.DatastoreBackend.

Note: Example of custom implementation can be found at ckanext.example_idatastorebackend

ckanext.datastore.backend.get_all_resources_ids_in_datastore() Helper for getting id of all resources in datastore. Uses get_all_ids of active datastore backend.

exception ckanext.datastore.backend.DatastoreException
exception ckanext.datastore.backend.InvalidDataError
Exception that’s raised if you try to add invalid data to the datastore.

For example if you have a column with type “numeric” and then you try to add a non-numeric value like “foo” to it, this exception should be raised.

class ckanext.datastore.backend.DatastoreBackend
Base class for all datastore backends.

Very simple example of implementation based on SQLite can be found in ckanext.example_idatastorebackend. In order to use it, set datastore.write_url to ‘example-sqlite:///tmp/database-name-on-your-choice’

Prop _backend mapping(schema, class) of all registered backends

Prop _active_backend current active backend

classmethod register_backends()
Register all backend implementations inside extensions.

classmethod set_active_backend(config)
Choose most suitable backend depending on configuration

Parameters config – configuration object

Return type ckan.common.CKANConfig

classmethod get_active_backend()
Return currently used backend

configure(config)
Configure backend, set inner variables, make some initial setup.

Parameters config – configuration object

Returns config

Return type CKANConfig

create(context, data_dict)
Create new resourct inside datastore.

Called by datastore_create.

Parameters data_dict – See ckanext.datastore.logic.action.datastore_create

Returns The newly created data object

Return type dictionary

upsert(context, data_dict)
Update or create resource depending on data_dict param.

Called by datastore_upsert.

Parameters data_dict – See ckanext.datastore.logic.action.datastore_upsert

Returns The modified data object

Return type dictionary

delete(context, data_dict)
Remove resource from datastore.

Called by datastore_delete.

Parameters data_dict – See ckanext.datastore.logic.action.datastore_delete

Returns Original filters sent.
Return type  dictionary

search (context, data_dict)
Base search.
Called by datastore_search.

Parameters

• data_dict – See ckanext.datastore.logic.action.datastore_search
• fields (list of dictionaries) – fields/columns and their extra metadata
• offset (int) – query offset value
• limit (int) – query limit value
• filters (list of dictionaries) – query filters
• total (int) – number of total matching records
• records (list of dictionaries) – list of matching results

Return type  dictionary with following keys

search_sql (context, data_dict)
Advanced search.
Called by datastore_search_sql. :param sql: a single search statement :type sql: string

Return type  dictionary

Parameters

• fields (list of dictionaries) – fields/columns and their extra metadata
• records (list of dictionaries) – list of matching results

resource_exists (id)
Define whether resource exists in datastore.

resource_fields (id)
Return dictionary with resource description.
Called by datastore_info. :returns: A dictionary describing the columns and their types.

resource_info (id)
Return DataDictionary with resource’s info - #3414

resource_id_from_alias (alias)
Convert resource’s alias to real id.

Parameters alias (string) – resource’s alias or id

Returns  real id of resource

Return type  string

get_all_ids ()
Return id of all resource registered in datastore.

Returns  all resources ids

Return type  list of strings

create_function (*args, **kwargs)
Called by datastore_function_create action.
drop_function(*args, **kwargs)
    Called by datastore_function_delete action.

### 3.10 Apps & Ideas

The old “Apps & Ideas” functionality to allow users to provide information on apps, ideas, visualizations, articles etc that are related to a specific dataset has been moved to a separate extension: ckanext-showcase.

### 3.11 Tag Vocabularies

New in version 1.7.

CKAN sites can have tag vocabularies, which are a way of grouping related tags together into custom fields.

For example, if you were making a site for music datasets, you might use a tag vocabulary to add two fields *Genre* and *Composer* to your site’s datasets, where each dataset can have one of the values Avant-Garde, Country or Jazz in its genre field, and one of the values Beethoven, Wagner, or Tchaikovsky in its composer field. In this example, genre and composer would be vocabularies and the values would be tags:

- Vocabulary: Genre
  - Tag: Avant-Garde
  - Tag: Country
  - Tag: Jazz

- Vocabulary: Composer
  - Tag: Beethoven
  - Tag: Wagner
  - Tag: Tchaikovsky

Of course, you could just add Avant-Garde, Beethoven, etc. to datasets as normal CKAN tags, but using tag vocabularies lets you define Avant-Garde, Country and Jazz as genres and Beethoven, Wagner and Tchaikovsky as composers, and lets you enforce restrictions such as that each dataset must have a genre and a composer, and that no dataset can have two genres or two composers, etc.

Another example use-case for tag vocabularies would be to add a *Country Code* field to datasets defining the geographical coverage of the dataset, where each dataset is assigned a country code such as *en*, *fr*, *de*, etc. See ckanext/example_idatasetform for a working example implementation of country codes as a tag vocabulary.

#### 3.11.1 Properties of Tag Vocabularies

- A CKAN website can have any number of vocabularies.
- Each vocabulary has an ID and name.
- Each tag either belongs to a vocabulary, or can be a free tag that doesn’t belong to any vocabulary (i.e. a normal CKAN tag).
- A dataset can have more than one tag from the same vocabulary, and can have tags from more than one vocabulary.
3.11.2 Using Vocabularies

To add a tag vocabulary to a site, a CKAN sysadmin must:

1. Call the `vocabulary_create()` action of the CKAN API to create the vocabulary and tags. See API guide.
2. Implement an `IDatasetForm` plugin to add a new field for the tag vocabulary to the dataset schema. See Extending guide.
3. Provide custom dataset templates to display the new field to users when adding, updating or viewing datasets in the CKAN web interface. See Theming guide.

See `ckanext/example_idatasetform` for a working example of these steps.

3.12 Form Integration

CKAN allows you to integrate its Edit Dataset and New Dataset forms into an external front-end. To that end, CKAN also provides a simple way to redirect these forms back to the external front-end upon submission.

3.12.1 Redirecting CKAN Forms

It is obviously simple enough for an external front-end to link to CKAN’s Edit Dataset and New Dataset forms, but once the forms are submitted, it would be desirable to redirect the user back to the external front-end, rather than CKAN’s dataset read page.

This is achieved with a parameter to the CKAN URL. The ‘return URL’ can be specified in two places:

1. Passed as a URL-encoded value with the parameter `return_to` in the link to CKAN’s form page.
2. Specified in the CKAN config keys `package_new_return_url` and `package_edit_return_url`.

(If the ‘return URL’ is supplied in both places, then the first takes precedence.)

Since the ‘return URL’ may need to include the dataset name, which could be changed by the user, CKAN replaces a known placeholder `<NAME>` with this value on redirect.

**Note:** Note that the downside of specifying the ‘return URL’ in the CKAN config is that the CKAN web interface becomes less usable on its own, since the user is hampered by the redirects to the external interface.

**Example**

An external front-end displays a dataset ‘ontariolandcoverv100’ here:

```
http://datadotgc.ca/dataset/ontariolandcoverv100
```

It displays a link to edit this dataset using CKAN’s form, which without the redirect would be:

```
http://ca.ckan.net/dataset/edit/ontariolandcoverv100
```

At first, it may seem that the return link should be `http://datadotgc.ca/dataset/ontariolandcoverv100`. But when the user edits this dataset, the name may change. So the return link needs to be:
And this is URL-encoded to become:

http%3A%2F%2Fdatadotgc.ca%2Fdataset%2F%3CNAME%3E

So, in summary, the edit link becomes:

http://ca.ckan.net/dataset/edit/ontariolandoverv100?return_to=http%3A%2F%2Fdatadotgc.ca%2Fdataset%2F%3CNAME%3E

During editing the dataset, the user changes the dataset name to *canadalandcover*, presses 'preview' and finally 'commit'. The user is now redirected back to the external front-end at:

http://datadotgc.ca/dataset/canadalandcover

The same functionality could be achieved by this line in the config file (*ca.ckan.net.ini*):

```ini
...  
[app:main]
package_edit_return_url = http://datadotgc.ca/dataset/<NAME>
...  
```

### 3.13 Linked Data and RDF

Linked data and RDF features for CKAN are provided by the ckanext-dcat extension:

https://github.com/ckan/ckanext-dcat

These features include the RDF serializations of CKAN datasets based on DCAT, that used to be generated using templates hosted on the main CKAN repo, eg:

- [http://demo.ckan.org/dataset/newcastle-city-council-payments-over-500.xml](http://demo.ckan.org/dataset/newcastle-city-council-payments-over-500.xml)
- [http://demo.ckan.org/dataset/newcastle-city-council-payments-over-500.n3](http://demo.ckan.org/dataset/newcastle-city-council-payments-over-500.n3)

ckanext-dcat offers many more features, including catalog-wide endpoints and harvesters to import RDF data into CKAN. Please check its documentation to know more about.

As of CKAN 2.5, the RDF templates have been moved out of CKAN core in favour of the ckanext-dcat customizable endpoints. Note that previous CKAN versions can still use the ckanext-dcat RDF representations, which will override the old ones served by CKAN core.

### 3.14 Background jobs

CKAN allows you to create jobs that run in the ‘background’, i.e. asynchronously and without blocking the main application. Such jobs can be created in *Extensions* or in core CKAN.

Background jobs can be essential to providing certain kinds of functionality, for example:
• Creating web-hooks that notify other services when certain changes occur (for example a dataset is updated)
• Performing processing or validation or on data (as done by the Archiver and DataStorer Extensions)

Basically, any piece of work that takes too long to perform while the main application is waiting is a good candidate for a background job.

**Note:** The current background job system is based on RQ and was introduced in CKAN 2.7. See *Migrating from CKAN's previous background job system* for details on how to migrate your jobs from the previous system introduced in CKAN 1.5.

### 3.14.1 Writing and enqueuing background jobs

**Note:** This section is only relevant for developers working on CKAN or an extension.

The core of a background job is a regular Python function. For example, here’s a very simply job function that logs a message:

```python
import logging
def log_job(msg, level=logging.INFO, logger=u'ckan'):
    u'Background job to log a message.'
    logger = logging.getLogger(logger)
    logger.log(level, msg)
```

And that’s it. Your job function can use all the usual Python features. Just keep in mind that your function will be run in a separate process by a *worker*, so your function should not depend on the current state of global variables, etc. Ideally your job function should receive all the information it needs via its arguments.

In addition, the module that contains your job function must be importable by the worker, which must also be able to get the function from its module. This means that nested functions, lambdas and instance methods cannot be used as job functions. While class methods of top-level classes can be used it’s best to stick to ordinary module-level functions.

**Note:** Background jobs do not support return values (since they run asynchronously there is no place to return those values to). If your job function produces a result then it needs to store that result, for example in a file or in CKAN’s database.

Once you have a job function, all you need to do is to use `ckan.lib.jobs.enqueue` to create an actual job out of it:

```python
import ckan.lib.jobs as jobs
jobs.enqueue(log_job, [u'My log message'])
```

This will place a job on the *job queue* where it can be picked up and executed by a worker.

**Note:** Extensions should use `ckan.plugins.toolkit.enqueue_job()` instead. It’s the same function but accessing it via `ckan.plugins.toolkit` decouples your code from CKAN’s internal structure.
The first argument to `enqueue` is the job function to use. The second is a list of the arguments which should be passed to the function. You can omit it in which case no arguments will be passed. You can also pass keyword arguments in a dict as the third argument:

```python
jobs.enqueue(log_job, [u'My log message'], {u'logger': u'ckanext.foo'})
```

You can also give the job a title which can be useful for identifying it when managing the job queue:

```python
jobs.enqueue(log_job, [u'My log message'], title=u'My log job')
```

**Accessing the database from background jobs**

Code running in a background job can access the CKAN database like any other CKAN code.

In particular, using the action functions to modify the database from within a background job is perfectly fine. Just keep in mind that while your job is running in the background, the CKAN main process or other background jobs may also modify the database. Hence a single call to an action function is atomic from your job’s view point, but between multiple calls there may be foreign changes to the database.

Special care has to be taken if your background job needs low-level access to the database, for example to modify SQLAlchemy model instances directly without going through an action function. Each background job runs in a separate process and therefore has its own SQLAlchemy session. Your code has to make sure that the changes it makes are properly contained in transactions and that you refresh your view of the database to receive updates where necessary. For these (and other) reasons it is recommended to use the action functions to interact with the database.

### 3.14.2 Running background jobs

Jobs are placed on the job queue, from which they can be retrieved and executed. Since jobs are designed to run asynchronously that happens in a separate process called a worker.

After it has been started, a worker listens on the queue until a job is enqueued. The worker then removes the job from the queue and executes it. Afterwards the worker waits again for the next job to be enqueued.

**Note:** Executed jobs are discarded. In particular, no information about past jobs is kept.

Workers can be started using the Run a background job worker command:

```bash
paster --plugin=ckan jobs worker --config=/etc/ckan/default/development.ini
```

The worker process will run indefinitely (you can stop it using CTRL+C).

**Note:** You can run multiple workers if your setup uses many or particularly long background jobs.

**Using Supervisor**

In a production setting, the worker should be run in a more robust way. One possibility is to use Supervisor.

First install Supervisor:

```bash
sudo apt-get install supervisor
```

Next copy the configuration file template:
Open `/etc/supervisor/conf.d/supervisor-ckan-worker.conf` in your favourite text editor and make sure all the settings suit your needs. If you installed CKAN in a non-default location (somewhere other than `/usr/lib/ckan/default`) then you will need to update the paths in the config file (see the comments in the file for details).

Restart Supervisor:

```
sudo service supervisor restart
```

The worker should now be running. To check its status, use

```
sudo supervisorctl status
```

You can restart the worker via

```
sudo supervisorctl restart ckan-worker:*
```

To test that background jobs are processed correctly you can enqueue a test job via

```
paster --plugin=ckan jobs test -c /etc/ckan/default/production.ini
```

The worker’s log (`/var/log/ckan-worker.log`) should then show how the job was processed by the worker.

In case you run into problems, make sure to check the logs of Supervisor and the worker:

```
cat /var/log/supervisor/supervisord.log
```
```
cat /var/log/ckan-worker.log
```

### 3.14.3 Managing background jobs

Once they are enqueued, background jobs can be managed via `paster` and the *web API*.

**List enqueues jobs**

- `paster jobs list`
- `ckan.logic.action.get.job_list()`

**Show details about a job**

- `paster jobs show`
- `ckan.logic.action.get.job_show()`

**Cancel a job**

A job that hasn’t been processed yet can be canceled via

- `paster jobs cancel`
- `ckan.logic.action.delete.job_cancel()`
Clear all enqueued jobs

- `paster jobs clear`
- `ckan.logic.action.delete.job_clear()`

Logging

Information about enqueued and processed background jobs is automatically logged to the CKAN logs. You may need to update your logging configuration to record messages at the `INFO` level for the messages to be stored.

3.14.4 Background job queues

By default, all functionality related to background jobs uses a single job queue that is specific to the current CKAN instance. However, in some situations it is useful to have more than one queue. For example, you might want to distinguish between short, urgent jobs and longer, less urgent ones. The urgent jobs should be processed even if a long and less urgent job is already running.

For such scenarios, the job system supports multiple queues. To use a different queue, all you have to do is pass the (arbitrary) queue name. For example, to enqueue a job at a non-default queue:

```python
jobs.enqueue(log_job, [u"I'm from a different queue!"], queue=u'my-own-queue')
```

Similarly, to start a worker that only listens to the queue you just posted a job to:

```bash
paster --plugin=ckan jobs worker my-own-queue --config=/etc/ckan/default/development.ini
```

See the documentation of the various functions and commands for details on how to use non-standard queues.

**Note:** If you create a custom queue in your extension then you should prefix the queue name using your extension’s name. See [Avoid name clashes](#).

Queue names are internally automatically prefixed with the CKAN site ID, so multiple parallel CKAN instances are not a problem.

3.14.5 Testing code that uses background jobs

Due to the asynchronous nature of background jobs, code that uses them needs to be handled specially when writing tests.

A common approach is to use the `mock` package to replace the `ckan.plugins.toolkit.enqueue_job` function with a mock that executes jobs synchronously instead of asynchronously:

```python
import mock
from ckan.tests import helpers

def synchronous_enqueue_job(job_func, args=None, kwargs=None, title=None):
    
    Synchronous mock for `ckan.plugins.toolkit.enqueue_job`.
```

(continues on next page)
Depending on how the function under test calls `enqueue_job` you might need to adapt where the mock is installed. See mock’s documentation for details.

### 3.14.6 Migrating from CKAN’s previous background job system

Before version 2.7 (starting from 1.5), CKAN offered a different background job system built around Celery. As of CKAN 2.8, that system is no longer available. You should therefore update your code to use the new system described above.

Migrating existing job functions is easy. In the old system, a job function would look like this:

```python
@celery.task(name=u'my_extension.echofunction')
def echo(message):
    print message
```

As described above, under the new system the same function would be simply written as

```python
def echo(message):
    print message
```

There is no need for a special decorator. In the new system there is also no need for registering your tasks via `setup.py`.

Migrating the code that enqueues a task is also easy. Previously it would look like this:

```python
celery.send_task(u'my_extension.echofunction', args=[u'Hello World'],
                 task_id=str(uuid.uuid4()))
```

With the new system, it looks as follows:

```python
import ckan.lib.jobs as jobs
jobs.enqueue(ckanext.my_extension.plugin.echo, [u'Hello World'])
```

As you can see, the new system does not use strings to identify job functions but uses the functions directly instead. There is also no need for creating a job ID, that will be done automatically for you.

### Supporting both systems at once

Not all CKAN installations will immediately update to CKAN 2.7. It might therefore make sense for you to support both the new and the old job system. That way you are ready when the old system is removed but can continue to
support older CKAN installations.

The easiest way to do that is to use ckanext-rq, which provides a back-port of the new system to older CKAN versions.

If you are unable to use ckanext-rq then you will need to write your code in such a way that it works on both systems. This could looks as follows. First split your Celery-based job functions into the job itself and its Celery handler. That is, change

```python
@celery.task(name=u'my_extension.echofunction')
def echo(message):
    print message
```

to

```python
def echo(message):
    print message
@celery.task(name=u'my_extension.echofunction')
def echo_celery(*args, **kwargs):
    echo(*args, **kwargs)
```

That way, you can call echo using the new system and use the name for Celery.

Then use the new system if it is available and fall back to Celery otherwise:

```python
def compat_enqueue(name, fn, args=None):
    
    Enqueue a background job using Celery or RQ.
    
    try:
        # Try to use RQ
        from ckan.plugins.toolkit import enqueue_job
        enqueue_job(fn, args=args)
    except ImportError:
        # Fallback to Celery
        import uuid
        from ckan.lib.celery_app import celery
        celery.send_task(name, args=args, task_id=str(uuid.uuid4()))
```

Use that function as follows for enqueuing a job:

```python
compat_enqueue(u'my_extension.echofunction',
  ckanext.my_extension.plugin.echo,
  [u'Hello World'])
```

### 3.15 Email notifications

CKAN can send email notifications to users, for example when a user has new activities on her dashboard. Once email notifications have been enabled by a site admin, each user of a CKAN site can turn email notifications on or off for herself by logging in and editing her user preferences. To enable email notifications for a CKAN site, a sysadmin must:

1. Setup a cron job or other scheduled job on a server to call CKAN’s send_email_notifications API action at regular intervals (e.g. hourly) and send any pending email notifications to users.

   On most UNIX systems you can setup a cron job by running `crontab -e` in a shell to edit your crontab file, and adding a line to the file to specify the new job. For more information run `man crontab` in a shell.
CKAN API actions can be called via the `paster post` command, which simulates an HTTP-request. For example, here is a crontab line to send out CKAN email notifications hourly:

```
@hourly echo '{} | /usr/lib/ckan/bin/paster --plugin=ckan post -c /etc/ckan/
→ production.ini /api/action/send_email_notifications > /dev/null
```

The `@hourly` can be replaced with `@daily`, `@weekly` or `@monthly`.

**Warning:** CKAN will not send email notifications for events older than the time period specified by the `ckan.email_notifications_since` config setting (default: 2 days), so your cron job should run more frequently than this. `@hourly` and `@daily` are good choices.

**Note:** Since `send_email_notifications` is an API action, it can be called from a machine other than the server on which CKAN is running, simply by POSTing an HTTP request to the CKAN API (you must be a sysadmin to call this particular API action). See API guide.

2. CKAN will not send out any email notifications, nor show the email notifications preference to users, unless the `ckan.activity_streams_email_notifications` option is set to `True`, so put this line in the `[app:main]` section of your CKAN config file:

```
ckan.activity_streams_email_notifications = True
```

3. Make sure that `ckan.site_url` is set correctly in the `[app:main]` section of your CKAN configuration file. This is used to generate links in the bodies of the notification emails. For example:

```
ckan.site_url = http://publicdata.eu
```

4. Make sure that `smtp.mail_from` is set correctly in the `[app:main]` section of your CKAN configuration file. This is the email address that CKAN’s email notifications will appear to come from. For example:

```
smtp.mail_from = mailman@publicdata.eu
```

This is combined with your `ckan.site_title` to form the `From:` header of the email that are sent, for example:

```
From: PublicData.eu <mailman@publicdata.eu>
```

5. If you do not have an SMTP server running locally on the machine that hosts your CKAN instance, you can change the Email Settings to send email via an external SMTP server. For example, these settings in the `[app:main]` section of your configuration file will send emails using a gmail account (not recommended for production websites!):

```
smtp.server = smtp.gmail.com:587
smtp.starttls = True
smtp.user = your_username@gmail.com
smtp.password = your_gmail_password
smtp.mail_from = your_username@gmail.com
```

6. You need to restart the web server for the new configuration to take effect. For example, if you are using Apache on Ubuntu, run this command in a shell:

```
sudo service apache2 reload
```
3.16 Page View Tracking

CKAN can track visits to pages of your site and use this tracking data to:

- Sort datasets by popularity
- Highlight popular datasets and resources
- Show view counts next to datasets and resources
- Show a list of the most popular datasets
- Export page-view data to a CSV file

See also:

ckanext-googleanalytics A CKAN extension that integrates Google Analytics into CKAN.

3.16.1 Enabling Page View Tracking

To enable page view tracking:

1. Set ckan.tracking_enabled to true in the [app:main] section of your CKAN configuration file (e.g. development.ini or production.ini):

   ```ini
   [app:main]
   ckan.tracking_enabled = true
   ```

   Save the file and restart your web server. CKAN will now record raw page view tracking data in your CKAN database as pages are viewed.

2. Setup a cron job to update the tracking summary data.

   For operations based on the tracking data CKAN uses a summarised version of the data, not the raw tracking data that is recorded “live” as page views happen. The `paster tracking update` and `paster search-index rebuild` commands need to be run periodically to update this tracking summary data.

   You can setup a cron job to run these commands. On most UNIX systems you can setup a cron job by running `crontab -e` in a shell to edit your crontab file, and adding a line to the file to specify the new job. For more information run `man crontab` in a shell. For example, here is a crontab line to update the tracking data and rebuild the search index hourly:

   ```bash
   @hourly /usr/lib/ckan/bin/paster --plugin=ckan tracking update -c /etc/ckan/production.ini && /usr/lib/ckan/bin/paster --plugin=ckan search-index rebuild -r -c /etc/ckan/production.ini
   ```

   Replace `/usr/lib/ckan/bin/` with the path to the `bin` directory of the virtualenv that you’ve installed CKAN into, and replace `/etc/ckan/production.ini` with the path to your CKAN configuration file.

   The `@hourly` can be replaced with `@daily`, `@weekly` or `@monthly`.

3.16.2 Retrieving Tracking Data

Tracking summary data for datasets and resources is available in the dataset and resource dictionaries returned by, for example, the `package_show()` API:
This can be used, for example, by custom templates to show the number of views next to datasets and resources. A dataset or resource’s recent count is its number of views in the last 14 days, the total count is all of its tracked views (including recent ones).

You can also export tracking data for all datasets to a CSV file using the `paster tracking export` command. For details, run `paster tracking -h`.

**Note:** Repeatedly visiting the same page will not increase the page’s view count! Page view counting is limited to one view per user per page per day.

### 3.16.3 Sorting Datasets by Popularity

Once you’ve enabled page view tracking on your CKAN site, you can view datasets most-popular-first by selecting Popular from the Order by: dropdown on the dataset search page:

The datasets are sorted by their number of recent views.

You can retrieve datasets most-popular-first from the CKAN API by passing `'sort': 'views_recent desc'` to the `package_search()` action. This could be used, for example, by a custom template to show a list of the most popular datasets on the site’s front page.

**Tip:** You can also sort datasets by total views rather than recent views. Pass `'sort': 'views_total desc'` to the `package_search()` API, or use the URL `/dataset?q=&sort=views_total+desc` in the web interface.
3.16.4 Highlighting Popular Datasets and Resources

Once you’ve enabled page view tracking on your CKAN site, popular datasets and resources (those with more than 10 views) will be highlighted with a “popular” badge and a tooltip showing the number of views:

![Popular Datasets and Resources Example]

3.17 Multilingual Extension

For translating CKAN’s web interface see Translating CKAN. In addition to user interface internationalization, a CKAN administrator can also enter translations into CKAN’s database for terms that may appear in the contents of datasets, groups or tags created by users. When a user is viewing the CKAN site, if the translation terms database contains a translation in the user’s language for the name or description of a dataset or resource, the name of a tag or group, etc. then the translated term will be shown to the user in place of the original.

3.17.1 Setup and Configuration

By default term translations are disabled. To enable them, you have to specify the multilingual plugins using the ckan.plugins setting in your CKAN configuration file, for example:

```bash
# List the names of CKAN extensions to activate.
ckan.plugins = multilingual_dataset multilingual_group multilingual_tag
```

Of course, you won’t see any terms getting translated until you load some term translations into the database. You can do this using the term_translation_update and term_translation_update_many actions of the CKAN API, See API guide for more details.

3.17.2 Loading Test Translations

If you want to quickly test the term translation feature without having to provide your own translations, you can load CKAN’s test translations into the database by running this command from your shell:
paster --plugin=ckan create-test-data translations

See *Command Line Interface* for more details.

### 3.17.3 Testing The Multilingual Extension

If you have a source installation of CKAN you can test the multilingual extension by running the tests located in `ckanext/multilingual/tests`. You must first install the packages needed for running CKAN tests into your virtual environment, and then run this command from your shell:

```
nosetests --ckan ckanext/multilingual/tests
```

See *Testing CKAN* for more information.

### 3.18 Stats Extension

CKAN’s stats extension analyzes your CKAN database and displays several tables and graphs with statistics about your site, including:

- Total number of datasets
- Dataset revisions per week
- Top-rated datasets
- Most-edited Datasets
- Largest groups
- Top tags
- Users owning most datasets

See also:

CKAN’s *built-in page view tracking feature*, which tracks visits to pages.

See also:

`ckanext-googleanalytics` A CKAN extension that integrates Google Analytics into CKAN.

#### 3.18.1 Enabling the Stats Extension

To enable the stats extensions add `stats` to the `ckan.plugins` option in your CKAN config file, for example:

```
ckan.plugins = stats
```

If you also set the `ckanext.stats.cache_enabled` option to `true`, CKAN will cache the stats for one day instead of calculating them each time a user visits the stats page.

#### 3.18.2 Viewing the Statistics

To view the statistics reported by the stats extension, visit the `/stats` page, for example: [http://demo.ckan.org/stats](http://demo.ckan.org/stats)
3.19 Configuration Options

The functionality and features of CKAN can be modified using many different configuration options. These are generally set in the **CKAN configuration file**, but some of them can also be set via Environment variables or at runtime.

### 3.19.1 Environment variables

Some of the CKAN configuration options can be defined as Environment variables on the server operating system. These are generally low-level critical settings needed when setting up the application, like the database connection, the Solr server URL, etc. Sometimes it can be useful to define them as environment variables to automate and orchestrate deployments without having to first modify the **CKAN configuration file**.

These options are only read at startup time to update the `config` object used by CKAN, but they won’t be accessed any more during the lifetime of the application.

CKAN environment variables names match the options in the configuration file, but they are always uppercase and prefixed with `CKAN_` (this prefix is added even if the corresponding option in the ini file does not have it), and replacing dots with underscores.

This is the list of currently supported environment variables, please refer to the entries in the **CKAN configuration file** section below for more details about each one:

```python
CONFIG_FROM_ENV_VARS = {
    'sqlalchemy.url': 'CKAN_SQLALCHEMY_URL',
    'ckan.datastore.write_url': 'CKAN_DATASTORE_WRITE_URL',
    'ckan.datastore.read_url': 'CKAN_DATASTORE_READ_URL',
    'ckan.redis.url': 'CKAN_REDIS_URL',
    'solr_url': 'CKAN_SOLR_URL',
    'solr_user': 'CKAN_SOLR_USER',
    'solr_password': 'CKAN_SOLR_PASSWORD',
    'ckan.site_id': 'CKAN_SITE_ID',
    'ckan.site_url': 'CKAN_SITE_URL',
    'ckan.storage_path': 'CKAN_STORAGE_PATH',
    'ckan.datapusher.url': 'CKAN_DATAPUSHER_URL',
    'smtp.server': 'CKAN_SMTP_SERVER',
    'smtp.starttls': 'CKAN_SMTP_STARTTLS',
    'smtp.user': 'CKAN_SMTP_USER',
    'smtp.password': 'CKAN_SMTP_PASSWORD',
    'smtp.mail_from': 'CKAN_SMTP_MAIL_FROM',
    'ckan.max_resource_size': 'CKAN_MAX_UPLOAD_SIZE_MB'
}
```

### 3.19.2 Updating configuration options during runtime

CKAN configuration options are generally defined before starting the web application (either in the **CKAN configuration file** or via Environment variables).

A limited number of configuration options can also be edited during runtime. This can be done on the administration interface or using the `config_option_update()` API action. Only `sysadmins` can edit these runtime-editable configuration options. Changes made to these configuration options will be stored on the database and persisted when the server is restarted.

Extensions can add (or remove) configuration options to the ones that can be edited at runtime. For more details on how to this check **Making configuration options runtime-editable**.

---

*3.19. Configuration Options* 111
3.19.3 CKAN configuration file

By default, the configuration file is located at /etc/ckan/default/development.ini or /etc/ckan/default/production.ini. This section documents all of the config file settings, for reference.

Note: After editing your config file, you need to restart your webserver for the changes to take effect.

Note: Unless otherwise noted, all configuration options should be set inside the [app:main] section of the config file (i.e. after the [app:main] line):

```
[DEFAULT]
...

[server:main]
use = egg: Paste#http
host = 0.0.0.0
port = 5000

# This setting will not work, because it’s outside of [app:main].
ckan.site_logo = /images/masaq.png

[app:main]
# This setting will work.
ckan.plugins = stats text_view recline_view
```

If the same option is set more than once in your config file, the last setting given in the file will override the others.

General Settings

debug

Example:

```
debug = False
```

Default value: False

This enables Pylons' interactive debugging tool, makes Fanstatic serve unminified JS and CSS files, and enables CKAN templates' debugging features.

Warning: This option should be set to False for a public site. With debug mode enabled, a visitor to your site could execute malicious commands.

ckan.legacy_route_mappings

Example:

```
ckan.legacy_route_mappings = {"home":"home.index", "about": "home.about",
"search": "dataset.search"}
```
This will prevent extensions from having broken routes if used older (pylons) route namings.

**Warning:** This configuration will be removed when migration to flask will be finished

### Repoze.who Settings

#### who.timeout

Example:

```python
who.timeout = 3600
```

Default value: None

This defines how long (in seconds) until a user is logged out after a period of inactivity. If the setting isn’t defined, the session doesn’t expire. Not active by default.

#### who.httponly

Default value: True

This determines whether the HttpOnly flag will be set on the repoze.who authorization cookie. The default in the absence of the setting is **True**. For enhanced security it is recommended to use the HttpOnly flag and not set this to **False**, unless you have a good reason for doing so.

#### who.secure

Example:

```python
who.secure = True
```

Default value: False

This determines whether the secure flag will be set for the repoze.who authorization cookie. If **True**, the cookie will be sent over HTTPS. The default in the absence of the setting is **False**.

#### who.samesite

Example:

```python
who.samesite = Strict
```

Default value: Lax

This determines whether the SameSite flag will be set for the repoze.who authorization cookie. Allowed values are **Lax** (the default one), **Strict** or **None**. If set to **None**, **who.secure** must be set to **True**.
**Database Settings**

**sqlalchemy.url**

Example:

```
sqlalchemy.url = postgres://tester:pass@localhost/ckantest3
```

This defines the database that CKAN is to use. The format is:

```
sqlalchemy.url = postgres://USERNAME:PASSWORD@HOST/DBNAME
```

**ckan.datastore.write_url**

Example:

```
ckan.datastore.write_url = postgresql://ckanuser:pass@localhost/datastore
```

The database connection to use for writing to the datastore (this can be ignored if you’re not using the DataStore extension). Note that the database used should not be the same as the normal CKAN database. The format is the same as in `sqlalchemy.url`.

**ckan.datastore.read_url**

Example:

```
ckan.datastore.read_url = postgresql://readonlyuser:pass@localhost/datastore
```

The database connection to use for reading from the datastore (this can be ignored if you’re not using the DataStore extension). The database used must be the same used in `ckan.datastore.write_url`, but the user should be one with read permissions only. The format is the same as in `sqlalchemy.url`.

**ckan.datastore.sqlalchemy.***

Example:

```
ckan.datastore.sqlalchemy.pool_size=10
ckan.datastore.sqlalchemy.max_overflow=20
```

Custom sqlalchemy config parameters used to establish the DataStore database connection. To get the list of all the available properties check the SQLAlchemy documentation

**ckan.datastore.default_fts_lang**

Example:

```
ckan.datastore.default_fts_lang = english
```
Default value: `english`
This can be ignored if you’re not using the `DataStore extension`.
The default language used when creating full-text search indexes and querying them. It can be overwritten by the user by passing the “`lang`” parameter to “`datastore_search`” and “`datastore_create`”.

**`ckan.datastore.default_fts_index_method`**

Example:

```python
ckan.datastore.default_fts_index_method = gist
```

Default value: `gist`
This can be ignored if you’re not using the `DataStore extension`.
The default method used when creating full-text search indexes. Currently it can be “`gin`” or “`gist`”. Refer to PostgreSQL’s documentation to understand the characteristics of each one and pick the best for your instance.

**`ckan.datastore.sqlsearch.enabled`**

Example:

```python
ckan.datastore.sqlsearch.enabled = False
```

Default value: `True`
This option allows you to disable the datastore_search_sql action function, and corresponding API endpoint if you do not wish it to be activated.

**Site Settings**

**`ckan.site_url`**

Example:

```python
ckan.site_url = http://scotdata.ckan.net
```

Default value: (an explicit value is mandatory)
Set this to the URL of your CKAN site. Many CKAN features that need an absolute URL to your site use this setting.
This setting should only contain the protocol (e.g. `http://`), host (e.g. `www.example.com`) and (optionally) the port (e.g. `:8080`). In particular, if you have mounted CKAN at a path other than `/` then the mount point must *not* be included in `ckan.site_url`. Instead, you need to set `ckan.root_path`.

**Important:** It is mandatory to complete this setting

**Warning:** This setting should not have a trailing `/` on the end.
apikey_header_name

Example:

```plaintext
apikey_header_name = API-KEY
```

Default value: X-CKAN-API-Key & Authorization

This allows another http header to be used to provide the CKAN API key. This is useful if network infrastructure blocks the Authorization header and X-CKAN-API-Key is not suitable.

ckan.cache_expires

Example:

```plaintext
ckan.cache_expires = 2592000
```

Default value: 0

This sets Cache-Control header's max-age value.

ckan.cache_enabled

Example:

```plaintext
ckan.cache_enabled = True
```

Default value: None

Controls if we're caching CKAN’s static files, if it’s serving them.

ckan.use_pylons_response_cleanup Middleware

Example:

```plaintext
ckan.use_pylons_response_cleanup Middleware = true
```

Default value: true

This enables middleware that clears the response string after it has been sent. This helps CKAN’s memory management if CKAN repeatedly serves very large requests.

ckan.mimetype_guess

Example:

```plaintext
ckan.mimetype_guess = file_ext
```

Default value: file_ext

There are three options for guessing the mimetype of uploaded or linked resources: file_ext, file_contents, None.

file_ext will guess the mimetype by the url first, then the file extension.

file_contents will guess the mimetype by the file itself, this tends to be inaccurate.
None will not store the mimetype for the resource.

**ckan.static_max_age**

Example:

```bash
ckan.static_max_age = 2592000
```

Default value: 3600

Controls CKAN static files’ cache max age, if we’re serving and caching them.

**ckan.tracking_enabled**

Example:

```bash
ckan.tracking_enabled = True
```

Default value: False

This controls if CKAN will track the site usage. For more info, read *Page View Tracking*.

**ckan.valid_url_schemes**

Example:

```bash
ckan.valid_url_schemes = http https ftp sftp
```

Default value: http https ftp

Controls what uri schemes are rendered as links.

**Authorization Settings**

More information about how authorization works in CKAN can be found the *Organizations and authorization* section.

**ckan.auth.anon_create_dataset**

Example:

```bash
ckan.auth.anon_create_dataset = False
```

Default value: False

Allow users to create datasets without registering and logging in.

**ckan.auth.create_unowned_dataset**

Example:
ckan.auth.create_unowned_dataset = False

Default value: True
Allow the creation of datasets not owned by any organization.

ckan.auth.create_dataset_if_not_in_organization

Example:
ckan.auth.create_dataset_if_not_in_organization = False

Default value: True
Allow users who are not members of any organization to create datasets, default: true. create_unowned_dataset must also be True, otherwise setting create_dataset_if_not_in_organization to True is meaningless.

ckan.auth.user_create_groups

Example:
ckan.auth.user_create_groups = True

Default value: False
Allow users to create groups.

ckan.auth.user_create_organizations

Example:
ckan.auth.user_create_organizations = False

Default value: True
Allow users to create organizations.

ckan.auth.user_delete_groups

Example:
ckan.auth.user_delete_groups = False

Default value: True
Allow users to delete groups.
**ckan.auth.user_delete_organizations**

Example:

```python
ckan.auth.user_delete_organizations = False
```

Default value: True
Allow users to delete organizations.

**ckan.auth.create_user_via_api**

Example:

```python
ckan.auth.create_user_via_api = False
```

Default value: False
Allow new user accounts to be created via the API by anyone. When False only sysadmins are authorised.

**ckan.auth.create_user_via_web**

Example:

```python
ckan.auth.create_user_via_web = True
```

Default value: True
Allow new user accounts to be created via the Web.

**ckan.auth.roles_that_cascade_to_sub_groups**

Example:

```python
ckan.auth.roles_that_cascade_to_sub_groups = admin editor
```

Default value: admin
Makes role permissions apply to all the groups down the hierarchy from the groups that the role is applied to.
e.g. a particular user has the ‘admin’ role for group ‘Department of Health’. If you set the value of this option to ‘admin’ then the user will automatically have the same admin permissions for the child groups of ‘Department of Health’ such as ‘Cancer Research’ (and its children too and so on).

**ckan.auth.public_user_details**

Example:

```python
ckan.auth.public_user_details = False
```

Default value: True
Restricts anonymous access to user information. If is set to False accessing users details when not logged in will raise a Not Authorized exception.
Note: This setting should be used when user registration is disabled (ckan.auth.create_user_via_web = False), otherwise users can just create an account to see other users details.

Search Settings

ckan.site_id

Example:

```bash
ckan.site_id = my_ckan_instance
```

CKAN uses Solr to index and search packages. The search index is linked to the value of the ckan.site_id, so if you have more than one CKAN instance using the same solr_url, they will each have a separate search index as long as their ckan.site_id values are different. If you are only running a single CKAN instance then this can be ignored.

Note, if you change this value, you need to rebuild the search index.

solr_url

Example:

```bash
```

Default value: http://127.0.0.1:8983/solr

This configures the Solr server used for search. The Solr schema found at that URL must be one of the ones in ckan/config/solr (generally the most recent one). A check of the schema version number occurs when CKAN starts.

Optionally, solr_user and solr_password can also be configured to specify HTTP Basic authentication details for all Solr requests.

Note: If you change this value, you need to rebuild the search index.

ckan.search.automatic_indexing

Example:

```bash
ckan.search.automatic_indexing = true
```

Default value: true

Make all changes immediately available via the search after editing or creating a dataset. Default is true. If for some reason you need the indexing to occur asynchronously, set this option to false.

Note: This is equivalent to explicitly load the synchronous_search plugin.
**ckan.search.solr_commit**

Example:

```bash
ckan.search.solr_commit = false
```

**Default value:** true

Make ckan commit changes solr after every dataset update change. Turn this to false if on solr 4.0 and you have automatic (soft)commits enabled to improve dataset update/create speed (however there may be a slight delay before dataset gets seen in results).

**ckan.search.show_all_types**

Example:

```bash
ckan.search.show_all_types = dataset
```

**Default value:** false

Controls whether a search page (e.g. /dataset) should also show custom dataset types. The default is false meaning that no search page for any type will show other types. true will show other types on the /dataset search page. Any other value (e.g. dataset or document will be treated as a dataset type and that type’s search page will show datasets of all types.

**ckan.search.default_include_private**

Example:

```bash
ckan.search.default_include_private = false
```

**Default value:** true

Controls whether the default search page (/dataset) should include private datasets visible to the current user or only public datasets visible to everyone.

**search.facets.limit**

Example:

```bash
search.facets.limit = 100
```

**Default value:** 50

Sets the default number of searched facets returned in a query.

**search.facets.default**

Example:

```bash
search.facets.default = 10
```

Default number of facets shown in search results. Default 10.
ckan.extra_resource_fields

Example:

```python
ckan.extra_resource_fields = alt_url
```

Default value: None
List of the extra resource fields that would be used when searching.

Redis Settings

ckan.redis.url

Example:

```python
ckan.redis.url = redis://localhost:7000/1
```

Default value: redis://localhost:6379/0
URL to your Redis instance, including the database to be used.
New in version 2.7.

CORS Settings

Cross-Origin Resource Sharing (CORS) can be enabled and controlled with the following settings:

ckan.cors.origin_allow_all

Example:

```python
ckan.cors.origin_allow_all = True
```

This setting must be present to enable CORS. If True, all origins will be allowed (the response header Access-Control-Allow-Origin is set to ‘*’). If False, only origins from the ckan.cors.origin_whitelist setting will be allowed.

ckan.cors.origin_whitelist

Example:

```python
```

A space separated list of allowable origins. This setting is used when ckan.cors.origin_allow_all = False.

Plugins Settings

ckan.plugins

Example:
ckan.plugins = disqus datapreview googleanalytics follower

Default value: stats text_view recline_view

Specify which CKAN plugins are to be enabled.

**Warning:** If you specify a plugin but have not installed the code, CKAN will not start.

Format as a space-separated list of the plugin names. The plugin name is the key in the `[ckan.plugins]` section of the extension’s `setup.py`. For more information on plugins and extensions, see [Extending guide](#).

**Note:** The order of the plugin names in the configuration file influences the order that CKAN will load the plugins in. As long as each plugin class is implemented in a separate Python module (i.e. in a separate Python source code file), the plugins will be loaded in the order given in the configuration file.

When multiple plugins are implemented in the same Python module, CKAN will process the plugins in the order that they’re given in the config file, but as soon as it reaches one plugin from a given Python module, CKAN will load all plugins from that Python module, in the order that the plugin classes are defined in the module.

For simplicity, we recommend implementing each plugin class in its own Python module.

Plugin loading order can be important, for example for plugins that add custom template files: templates found in template directories added earlier will override templates in template directories added later.

**Todo:** Fix CKAN’s plugin loading order to simply load all plugins in the order they’re given in the config file, regardless of which Python modules they’re implemented in.

**ckanext.stats.cache_enabled**

Example:

```
ckanext.stats.cache_enabled = True
```

Default value: True

This controls if we’ll use the 1 day cache for stats.

**ckan.resource_proxy.max_file_size**

Example:

```
ckan.resource_proxy.max_file_size = 1048576
```

Default value: 1048576 (1 MB)

This sets the upper file size limit for in-line previews. Increasing the value allows CKAN to preview larger files (e.g. PDFs) in-line; however, a higher value might cause time-outs, or unresponsive browsers for CKAN users with lower bandwidth. If left commented out, CKAN will default to 1 MB.
**ckan.resource_proxy.chunk_size**

Example:

```plaintext
ckan.resource_proxy.chunk_size = 8192
```

Default value: 4096

This sets size of the chunk to read and write when proxying. Raising this value might save some CPU cycles. It makes no sense to lower it below the page size, which is default.

**Front-End Settings**

**ckan.site_title**

Example:

```plaintext
ckan.site_title = Open Data Scotland
```

Default value: CKAN

This sets the name of the site, as displayed in the CKAN web interface.

**ckan.site_description**

Example:

```plaintext
ckan.site_description = The easy way to get, use and share data
```

Default value: (none)

This is for a description, or tag line for the site, as displayed in the header of the CKAN web interface.

**ckan.site_intro_text**

Example:

```plaintext
ckan.site_intro_text = Nice introductory paragraph about CKAN or the site in general.
```

Default value: (none)

This is for an introductory text used in the default template’s index page.

**ckan.site_logo**

Example:

```plaintext
ckan.site_logo = /images/ckan_logo_fullname_long.png
```

Default value: (none)

This sets the logo used in the title bar.
**ckan.site_about**

Example:

```
ckan.site_about = A _community-driven_ catalogue of _open data_ for the Greenfield_
˓→area.
```

Default value:

```
<p>CKAN is the world’s leading open-source data portal platform.</p>
<p>CKAN is a complete out-of-the-box software solution that makes data
accessible and usable - by providing tools to streamline publishing, sharing,
finding and using data (including storage of data and provision of robust data
APIs). CKAN is aimed at data publishers (national and regional governments,
companies and organizations) wanting to make their data open and available.</p>
<p>CKAN is used by governments and user groups worldwide and powers a variety
of official and community data portals including portals for local, national
and international government, such as the UK’s <a href="http://data.gov.uk">data.gov.uk</a>
and the European Union’s <a href="http://publicdata.eu">publicdata.eu</a>,
the Brazilian <a href="http://dados.gov.br">dados.gov.br</a>, Dutch and
Netherlands government portals, as well as city and municipal sites in the US,
UK, Argentina, Finland and elsewhere.</p>
```

Format tips:

- multiline strings can be used by indenting following lines
- the format is Markdown

**Note:** Whilst the default text is translated into many languages (switchable in the page footer), the text in this configuration option will not be translatable. For this reason, it’s better to overload the snippet in `home/snippets/about_text.html`. For more information, see Theming guide.

**ckan.main_css**

Example:

```
ckan.main_css = /base/css/my-custom.css
```

Default value: `/base/css/main.css`

With this option, instead of using the default `main.css`, you can use your own.

**ckan.favicon**

Example:

Default value: /images/icons/ckan.ico
This sets the site’s favicon. This icon is usually displayed by the browser in the tab heading and bookmark.

ckan.legacy_templates

Example:

ckan.legacy_templates = True

Default value: False
This controls if the legacy genshi templates are used.

Note: This option is deprecated and has no effect any more.

ckan.datasets_per_page

Example:

ckan.datasets_per_page = 10

Default value: 20
This controls the pagination of the dataset search results page. This is the maximum number of datasets viewed per page of results.

package_hide_extras

Example:

package_hide_extras = my_private_field other_field

Default value: (empty)
This sets a space-separated list of extra field key values which will not be shown on the dataset read page.

Warning: While this is useful to e.g. create internal notes, it is not a security measure. The keys will still be available via the API and in revision diffs.

ckan.dumps_url

If there is a page which allows you to download a dump of the entire catalogue then specify the URL here, so that it can be advertised in the web interface. For example:

ckan.dumps_url = http://ckan.net/dump/
For more information on using dumpfiles, see *Exporting Datasets to JSON Lines*.

**ckan.dumps_format**

If there is a page which allows you to download a dump of the entire catalogue then specify the format here, so that it can be advertised in the web interface. `dumps_format` is just a string for display. Example:

```python
ckan.dumps_format = CSV/JSON
```

**ckan.recaptcha.publickey**

The public key for your reCAPTCHA account, for example:

```python
ckan.recaptcha.publickey = 6Lc...-KLc
```

To get a reCAPTCHA account, sign up at: http://www.google.com/recaptcha

**ckan.recaptcha.privatekey**

The private key for your reCAPTCHA account, for example:

```python
ckan.recaptcha.privatekey = 6Lc...-jP
```

Setting both `ckan.recaptcha.publickey` and `ckan.recaptcha.privatekey` adds captcha to the user registration form. This has been effective at preventing bots registering users and creating spam packages.

**ckan.featured_groups**

Example:

```python
ckan.featured_groups = group_one
```

Default Value: (empty)

Defines a list of group names or group ids. This setting is used to display a group and datasets on the home page in the default templates (1 group and 2 datasets are displayed).

**ckan.featured_orgs**

Example:

```python
ckan.featured_orgs = org_one
```

Default Value: (empty)

Defines a list of organization names or ids. This setting is used to display an organization and datasets on the home page in the default templates (1 group and 2 datasets are displayed).
**ckan.gravatar_default**

Example:

```plaintext
dEFAULT VALUE: identicon
This controls the default gravatar avatar, in case the user has none.
```

**ckan.debug_supress_header**

Example:

```plaintext
dEFAULT VALUE: False
This configures if the debug information showing the controller and action receiving the request being is shown in the header.
```

**Note:** This info only shows if debug is set to True.

**Resource Views Settings**

**ckan.views.default_views**

Example:

```plaintext
dEFAULT VALUE: image_view recline_view
Defines the resource views that should be created by default when creating or updating a dataset. From this list only the views that are relevant to a particular resource format will be created. This is determined by each individual view. If not present (or commented), the default value is used. If left empty, no default views are created.
```

**Note:** You must have the relevant view plugins loaded on the ckan.plugins setting to be able to create the default views, eg:

```plaintext
dEFAULT VALUE: False
```

**ckan.preview.json_formats**

Example:
ckan.preview.json_formats = json

Default value: json
Space-delimited list of JSON based resource formats that will be rendered by the Text view plugin (text_view)

**ckan.preview.xml_formats**

Example:

ckan.preview.xml_formats = xml rdf rss

Default value: xml rdf rdf+xml owl+xml atom rss
Space-delimited list of XML based resource formats that will be rendered by the Text view plugin (text_view)

**ckan.preview.text_formats**

Example:

ckan.preview.text_formats = text plain

Default value: text plain text/plain
Space-delimited list of plain text based resource formats that will be rendered by the Text view plugin (text_view)

**ckan.preview.image_formats**

Example:

ckan.preview.image_formats = png jpeg jpg gif

Default value: png jpeg jpg gif
Space-delimited list of image-based resource formats that will be rendered by the Image view plugin (image_view)

**ckan.recline.dataproxy_url**

Example:

ckan.recline.dataproxy_url = https://mydataproxy.example.com

Default value: //jsonpdataproxy.appspot.com
Custom URL to a self-hosted DataProxy instance. The DataProxy is an external service currently used to stream data in JSON format to the Recline-based views when data is not on the DataStore. The main instance is deprecated and will be eventually shut down, so users that require it can host an instance themselves and use this configuration option to point Recline to it.
**Theming Settings**

**ckan.template_head_end**

HTML content to be inserted just before `</head>` tag (e.g. extra stylesheet)

Example:

```python
ckan.template_head_end = '<link rel="stylesheet" href="http://mysite.org/css/custom.css" type="text/css">'
```

You can also have multiline strings. Just indent following lines. e.g.:

```python
ckan.template_head_end =
 '<link rel="stylesheet" href="/css/extra1.css" type="text/css">
 '<link rel="stylesheet" href="/css/extra2.css" type="text/css">
```

**Note:** This is only for legacy code, and shouldn’t be used anymore.

**ckan.template_footer_end**

HTML content to be inserted just before `</body>` tag (e.g. Google Analytics code).

**Note:** you can have multiline strings (just indent following lines)

Example (showing insertion of Google Analytics code):

```python
ckan.template_footer_end = ' <!-- Google Analytics -->
 <script src='http://www.google-analytics.com/ga.js' type='text/javascript'></script>
 <script type="text/javascript">
   try {
     var pageTracker = _gat._getTracker("XXXXXXXXX");
     pageTracker._setDomainName(".ckan.net");
     pageTracker._trackPageview();
   } catch(err) {}
 </script>
 <!-- /Google Analytics -->
```

**Note:** This is only for legacy code, and shouldn’t be used anymore.

**ckan.template_title_delimnater**

Example:

```python
ckan.template_title_delimnater = |
```

Default value: -

This sets the delimiter between the site’s subtitle (if there’s one) and its title, in HTML’s `<title>`. 

---

130 Chapter 3. Maintainer’s guide
extra_template_paths

Example:

```
extra_template_paths = /home/okfn/brazil_ckan_config/templates
```

Use this option to specify where CKAN should look for additional templates, before reverting to the `ckan/templates` folder. You can supply more than one folder, separating the paths with a comma (,).

For more information on theming, see Theming guide.

extra_public_paths

Example:

```
extra_public_paths = /home/okfn/brazil_ckan_config/public
```

To customise the display of CKAN you can supply replacements for static files such as HTML, CSS, script and PNG files. Use this option to specify where CKAN should look for additional files, before reverting to the `ckan/public` folder. You can supply more than one folder, separating the paths with a comma (,).

For more information on theming, see Theming guide.

ckan.base_public_folder

Example:

```
ckan.base_public_folder = public
```

Default value: `public`

This config option is used to configure the base folder for static files used by CKAN core. It’s used to determine which version of Bootstrap to be used. It accepts two values: `public` (Bootstrap 3, the default value from CKAN 2.8 onwards) and `public-bs2` (Bootstrap 2, used until CKAN 2.7).

It must be used in conjunction with `ckan.base_templates_folder` in order for it to properly function. Also, you can’t use for example Bootstrap 3 for static files and Bootstrap 2 for templates or vice versa.

**Note:** Starting with CKAN 2.8, Bootstrap 3 will be used as a default.

ckan.base_templates_folder

Example:

```
ckan.base_templates_folder = templates
```

Default value: `templates`

This config option is used to configure the base folder for templates used by CKAN core. It’s used to determine which version of Bootstrap to be used. It accepts two values: `templates` (Bootstrap 3, the default value from CKAN 2.8 onwards) and `templates-bs2` (Bootstrap 2, used until CKAN 2.7).

3.19. Configuration Options 131
It must be used in conjunction with `ckan.base_public_folder` in order for it to properly function. Also, you can’t use for example Bootstrap 3 for templates and Bootstrap 2 for static files or vice versa.

Note: Starting with CKAN 2.8, Bootstrap 3 will be used as a default.

**Storage Settings**

**ckan.storage_path**

**Example:**

```
ckan.storage_path = /var/lib/ckan
```

Default value: `None`

This defines the location of where CKAN will store all uploaded data.

**ckan.max_resource_size**

**Example:**

```
ckan.max_resource_size = 100
```

Default value: 10

The maximum in megabytes a resources upload can be.

**ckan.max_image_size**

**Example:**

```
ckan.max_image_size = 10
```

Default value: 2

The maximum in megabytes an image upload can be.

**ofs.impl**

Example:

```
ofs.impl = pairtree
```

Default value: `None`

Defines the storage backend used by CKAN: `pairtree` for local storage, `s3` for Amazon S3 Cloud Storage or `google` for Google Cloud Storage. Note that each of these must be accompanied by the relevant settings for each backend described below.

Deprecated, only available option is now pairtree. This must be used nonetheless if upgrading for CKAN 2.1 in order to keep access to your old pairtree files.

**ofs.storage_dir**

Example:

```
ofs.storage_dir = /data/uploads/
```
Default value: None

Only used with the local storage backend. Use this to specify where uploaded files should be stored, and also to turn on the handling of file storage. The folder should exist, and will automatically be turned into a valid pairtree repository if it is not already.

Deprecated, please use ckan.storage_path. This must be used nonetheless if upgrading for CKAN 2.1 in order to keep access to your old pairtree files.

**DataPusher Settings**

**ckan.datapusher.formats**

Example:

```
ckan.datapusher.formats = csv xls
```

Default value: `csv xls xlsx tsv application/csv application/vnd.ms-excel application/vnd.openxmlformats-officedocument.spreadsheetml.sheet`

File formats that will be pushed to the DataStore by the DataPusher. When adding or editing a resource which links to a file in one of these formats, the DataPusher will automatically try to import its contents to the DataStore.

**ckan.datapusher.url**

Example:

```
ckan.datapusher.url = http://127.0.0.1:8800/
```

DataPusher endpoint to use when enabling the datapusher extension. If you installed CKAN via *Installing CKAN from package*, the DataPusher was installed for you running on port 8800. If you want to manually install the DataPusher, follow the installation instructions.

**ckan.datapusher.callback_url_base**

Example:

```
ckan.datapusher.callback_url_base = http://ckan:5000/
```

Default value: Value of `ckan.site_url`

Alternative callback URL for DataPusher when performing a request to CKAN. This is useful on scenarios where the host where DataPusher is running can not access the public CKAN site URL.

**ckan.datapusher.assume_task_stale_after**

Example:

```
ckan.datapusher.assume_task_stale_after = 86400
```

Default value: 3600 (one hour)

In case a DataPusher task gets stuck and fails to recover, this is the minimum amount of time (in seconds) after a resource is submitted to DataPusher that the resource can be submitted again.

3.19. Configuration Options
User Settings

`ckan.user_list_limit`

Example:

```
ckan.user_list_limit = 50
```

Default value: 20

This controls the number of users to show in the Users list. By default, it shows 20 users.

Activity Streams Settings

`ckan.activity_streams_enabled`

Example:

```
ckan.activity_streams_enabled = False
```

Default value: True

Turns on and off the activity streams used to track changes on datasets, groups, users, etc.

`ckan.activity_streams_email_notifications`

Example:

```
ckan.activity_streams_email_notifications = False
```

Default value: False

Turns on and off the activity streams’ email notifications. You’d also need to setup a cron job to send the emails. For more information, visit Email notifications.

`ckan.activity_list_limit`

Example:

```
ckan.activity_list_limit = 31
```

Default value: infinite

This controls the number of activities to show in the Activity Stream. By default, it shows everything.

`ckan.email_notifications_since`

Example:

```
ckan.email_notifications_since = 2 days
```
Default value: infinite

Email notifications for events older than this time delta will not be sent. Accepted formats: ‘2 days’, ‘14 days’, ‘4:35:00’ (hours, minutes, seconds), ’7 days, 3:23:34’, etc.

**ckan.hide_activity_from_users**

Example:

```python
ckan.hide_activity_from_users = sysadmin
```

Hides activity from the specified users from activity stream. If unspecified, it’ll use `ckan.site_id` to hide activity by the site user. The site user is a sysadmin user on every ckan user with a username that’s equal to `ckan.site_id`. This user is used by ckan for performing actions from the command-line.

**Feeds Settings**

**ckan.feeds.author_name**

Example:

```python
ckan.feeds.author_name = Michael Jackson
```

Default value: (none)

This controls the feed author’s name. If unspecified, it’ll use `ckan.site_id`.

**ckan.feeds.author_link**

Example:

```python
ckan.feeds.author_link = http://okfn.org
```

Default value: (none)

This controls the feed author’s link. If unspecified, it’ll use `ckan.site_url`.

**ckan.feeds.authority_name**

Example:

```python
ckan.feeds.authority_name = http://okfn.org
```

Default value: (none)

The domain name or email address of the default publisher of the feeds and elements. If unspecified, it’ll use `ckan.site_url`.

**ckan.feeds.date**

Example:
ckan.feeds.date = 2012-03-22

Default value: (none)

A string representing the default date on which the authority_name is owned by the publisher of the feed.

**Internationalisation Settings**

**ckan.locale_default**

Example:

ckan.locale_default = de

Default value: en (English)

Use this to specify the locale (language of the text) displayed in the CKAN Web UI. This requires a suitable mo file installed for the locale in the ckan/i18n. For more information on internationalization, see Translating CKAN. If you don’t specify a default locale, then it will default to the first locale offered, which is by default English (alter that with ckan.locales_offered and ckan.locales_filtered_out).

**ckan.locales_offered**

Example:

ckan.locales_offered = en de fr

Default value: (none)

By default, all locales found in the ckan/i18n directory will be offered to the user. To only offer a subset of these, list them under this option. The ordering of the locales is preserved when offered to the user.

**ckan.locales_filtered_out**

Example:

ckan.locales_filtered_out = pl ru

Default value: (none)

If you want to not offer particular locales to the user, then list them here to have them removed from the options.

**ckan.locale_order**

Example:

ckan.locale_order = fr de

Default value: (none)

If you want to specify the ordering of all or some of the locales as they are offered to the user, then specify them here in the required order. Any locales that are available but not specified in this option, will still be offered at the end of the list.
ckan.i18n_directory

Example:

```
ckan.i18n_directory = /opt/locales/i18n/
```

Default value: (none)

By default, the locales are searched for in the ckan/i18n directory. Use this option if you want to use another folder.

ckan.i18n.extra_directory

Example:

```
ckan.i18n.extra_directory = /opt/ckan/extra_translations/
```

Default value: (none)

If you wish to add extra translation strings and have them merged with the default ckan translations at runtime you can specify the location of the extra translations using this option.

ckan.i18n.extra_gettext_domain

Example:

```
ckan.i18n.extra_gettext_domain = mydomain
```

Default value: (none)

You can specify the name of the gettext domain of the extra translations. For example if your translations are stored as i18n/<locale>/LC_MESSAGES/somedomain.mo you would want to set this option to somedomain

ckan.i18n.extra_locales

Example:

```
ckan.i18n.extra_locales = fr es de
```

Default value: (none)

If you have set an extra i18n directory using ckan.i18n.extra_directory, you should specify the locales that have been translated in that directory in this option.

ckan.i18n.rtl_languages

Example:

```
ckan.i18n.rtl_languages = he ar fa_IR
```

Default value: he ar fa_IR

Allows to modify the right-to-left languages
**ckan.i18n.rtl_css**

Example:

```python
ckan.i18n.rtl_css = /base/css/my-custom-rtl.css
```

Default value: /base/css/rtl.css

Allows to override the default rtl css file used for the languages defined in `ckan.i18n.rtl_languages`.

---

**ckan.display_timezone**

Example:

```python
ckan.display_timezone = Europe/Zurich
```

Default value: UTC

By default, all datetimes are considered to be in the UTC timezone. Use this option to change the displayed dates on the frontend. Internally, the dates are always saved as UTC. This option only changes the way the dates are displayed.

The valid values for this options [can be found at pytz](http://pytz.sourceforge.net/#helpers) (`pytz.all_timezones`). You can specify the special value `server` to use the timezone settings of the server, that is running CKAN.

---

**ckan.root_path**

Example:

```python
ckan.root_path = /my/custom/path/{{LANG}}/foo
```

Default value: (none)

This setting is used to construct URLs inside CKAN. It specifies two things:

- **At which path CKAN is mounted**: By default it is assumed that CKAN is mounted at `/`, i.e. at the root of your web server. If you have configured your web server to serve CKAN from a different mount point then you need to duplicate that setting here.

- **Where the locale is added to an URL**: By default, URLs are formatted as `/some/url` when using the default locale, or `/de/some/url` when using the de locale, for example. When `ckan.root_path` is set it must include the string `{{LANG}}`, which will be replaced by the locale.

**Important**: The setting must contain `{{LANG}}` exactly as written here. Do not add spaces between the brackets.

See also:
The host of your CKAN installation can be set via `ckan.site_url`.

---

**ckan.resource_formats**

Example:: ckan.resource_formats = /path/to/resource_formats
Default value: ckan/config/resource_formats.json

The purpose of this file is to supply a thorough list of resource formats and to make sure the formats are normalized when saved to the database and presented.

The format of the file is a JSON object with following format:

```json
["Format", "Description", "Mimetype", ["List of alternative representations"]]
```

Please look in ckan/config/resource_formats.json for full details and as an example.

**Form Settings**

**package_new_return_url**

The URL to redirect the user to after they’ve submitted a new package form, example:

```python
package_new_return_url = http://datadotgc.ca/new_dataset_complete?name=<NAME>
```

This is useful for integrating CKAN’s new dataset form into a third-party interface, see Form Integration.

The `<NAME>` string is replaced with the name of the dataset created.

**package_edit_return_url**

The URL to redirect the user to after they’ve submitted an edit package form, example:

```python
package_edit_return_url = http://datadotgc.ca/dataset/<NAME>
```

This is useful for integrating CKAN’s edit dataset form into a third-party interface, see Form Integration.

The `<NAME>` string is replaced with the name of the dataset that was edited.

**licenses_group_url**

A url pointing to a JSON file containing a list of license objects. This list determines the licenses offered by the system to users, for example when creating or editing a dataset.

This is entirely optional - by default, the system will use an internal cached version of the CKAN list of licenses available from the http://licenses.opendefinition.org/licenses/groups/ckan.json.

More details about the license objects - including the license format and some example license lists - can be found at the Open Licenses Service.

Examples:

```python
licenses_group_url = file:///path/to/my/local/json-list-of-licenses.json
licenses_group_url = http://licenses.opendefinition.org/licenses/groups/od.json
```

**Email Settings**

**smtp.server**

Example:
smtp.server = smtp.example.com:587

Default value: None
The SMTP server to connect to when sending emails with optional port.

smtp.starttls

Example:

smtp.starttls = True

Default value: None
Whether or not to use STARTTLS when connecting to the SMTP server.

smtp.user

Example:

smtp.user = username@example.com

Default value: None
The username used to authenticate with the SMTP server.

smtp.password

Example:

smtp.password = yourpass

Default value: None
The password used to authenticate with the SMTP server.

smtp.mail_from

Example:

smtp.mail_from = ckan@example.com

Default value: None
The email address that emails sent by CKAN will come from. Note that, if left blank, the SMTP server may insert its own.

eemail_to

Example:
email_to = errors@example.com

Default value: None
This controls where the error messages will be sent to.

**error_email_from**

Example:

```text
error_email_from = ckan-errors@example.com
```

Default value: None
This controls from which email the error messages will come from.
This section documents CKAN’s API, for developers who want to write code that interacts with CKAN sites and their data.

CKAN’s Action API is a powerful, RPC-style API that exposes all of CKAN’s core features to API clients. All of a CKAN website’s core functionality (everything you can do with the web interface and more) can be used by external code that calls the CKAN API. For example, using the CKAN API your app can:

- Get JSON-formatted lists of a site’s datasets, groups or other CKAN objects:
  - http://demo.ckan.org/api/3/action/package_list
  - http://demo.ckan.org/api/3/action/group_list
  - http://demo.ckan.org/api/3/action/tag_list
- Get a full JSON representation of a dataset, resource or other object:
  - http://demo.ckan.org/api/3/action/package_show?id=adur_district_spending
  - http://demo.ckan.org/api/3/action/tag_show?id=gold
  - http://demo.ckan.org/api/3/action/group_show?id=data-explorer
- Search for packages or resources matching a query:
- Create, update and delete datasets, resources and other objects
- Get an activity stream of recently changed datasets on a site:
  - http://demo.ckan.org/api/3/action/recently_changed_packages_activity_list

Note: CKAN’s FileStore and DataStore have their own APIs, see:

- FileStore and file uploads
- DataStore extension
4.1 Legacy APIs

Note: For documentation of CKAN’s legacy API’s, see Legacy APIs.

4.1.1 Search API

Search resources are available at published locations. They are represented with a variety of data formats. Each resource location supports a number of methods.

The data formats of the requests and the responses are defined below.

Search Resources

Here are the published resources of the Search API.

<table>
<thead>
<tr>
<th>Search Resource</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dataset Search</td>
<td>/search/dataset</td>
</tr>
<tr>
<td>Resource Search</td>
<td>/search/resource</td>
</tr>
<tr>
<td>Revision Search</td>
<td>/search/revision</td>
</tr>
<tr>
<td>Tag Counts</td>
<td>/tag_counts</td>
</tr>
</tbody>
</table>

See below for more information about dataset and revision search parameters.

Search Methods

Here are the methods of the Search API.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Method</th>
<th>Request</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dataset Search</td>
<td>POST</td>
<td>Dataset-Search-Params</td>
<td>Dataset-Search-Response</td>
</tr>
<tr>
<td>Resource Search</td>
<td>POST</td>
<td>Resource-Search-Params</td>
<td>Resource-Search-Response</td>
</tr>
<tr>
<td>Revision Search</td>
<td>POST</td>
<td>Revision-Search-Params</td>
<td>Revision-List</td>
</tr>
<tr>
<td>Tag Counts</td>
<td>GET</td>
<td></td>
<td>Tag-Count-List</td>
</tr>
</tbody>
</table>

It is also possible to supply the search parameters in the URL of a GET request, for example /api/search/dataset?q=geodata&allfields=1.
**Search Formats**

Here are the data formats for the Search API.

<table>
<thead>
<tr>
<th>Name</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dataset-Search-Params</td>
<td>Resource-Search-Params Revision-Search-Params { Param-Key: Param-Value, Param-Key: Param-Value, . . . } See below for full details of search parameters across the various domain objects.</td>
</tr>
<tr>
<td>Dataset-Search-Response</td>
<td>{ count: Count-int, results: [Dataset, Dataset, . . . ] }</td>
</tr>
<tr>
<td>Revision-List</td>
<td>[ Revision-Id, Revision-Id, Revision-Id, . . . ] NB: Ordered with youngest revision first. NB: Limited to 50 results at a time.</td>
</tr>
<tr>
<td>Tag-Count-List</td>
<td>[ [Name-String, Integer], [Name-String, Integer], . . . ]</td>
</tr>
</tbody>
</table>

**Dataset Parameters**

<table>
<thead>
<tr>
<th>Param-Key</th>
<th>Param-Value</th>
<th>Examples</th>
<th>Notes</th>
</tr>
</thead>
</table>
| q         | Search-String | q=geodata  
 q=government+sweden  
 q=%22drug%20abuse%22  
 q=tags:"river pollution" | Criteria to search the dataset fields for. URL-encoded search text. (You can also concatenate words with a ‘+’ symbol in a URL.) Search results must contain all the specified words. You can also search within specific fields. |
| qjson     | JSON encoded options | [‘q’: ‘geodata’] | All search parameters can be json-encoded and supplied to this parameter as a more flexible alternative in GET requests. |
| title, tags, notes, groups, author, maintainer, update_frequency, or any ‘extra’ field name e.g. department | Search-String | title=uk&amp;tags=health  
 department=environment  
 tags=health&amp;tags=pollution  
 tags=river%20pollution | Search in a particular a field. |
| order_by  | field-name (default=rank) | order_by=name | Specify either rank or the field to sort the results by |
| offset, limit | result-int (defaults: offset=0, limit=20) | offset=40&amp;limit=20 | Pagination options. Offset is the number of the first result and limit is the number of results to return. |
| all_fields | 0 (default) or 1 | all_fields=1 | Each matching search result is given as either a dataset name (0) or the full dataset record (1). |
Note: filter_by_openness and filter_by_downloadable were dropped from CKAN version 1.5 onwards.

Note: Only public datasets can be accessed via the legacy search API, regardless of the provided authorization. If you need to access private datasets via the API you will need to use the package_search method of the API guide.

Resource Parameters

<table>
<thead>
<tr>
<th>Param-Key</th>
<th>Param-Value</th>
<th>Example</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>url, format, description</td>
<td>Search-String</td>
<td>url=statistics.org format=xls description=Research+Institute</td>
<td>Criteria to search the dataset fields for. URL-encoded search text. This search string must be found somewhere within the field to match. Case insensitive.</td>
</tr>
<tr>
<td>qjson</td>
<td>JSON encoded options</td>
<td>['url':'www.statistics.org']</td>
<td>All search parameters can be json-encoded and supplied to this parameter as a more flexible alternative in GET requests.</td>
</tr>
<tr>
<td>hash</td>
<td>Search-String</td>
<td>hash=b0d7c260-35d4-42ab-9e3d-c1f4db9bc2f0</td>
<td>Searches for an exact match of the hash field. An exact match or match up to the length of the hash given.</td>
</tr>
<tr>
<td>all_fields</td>
<td>0 (default) or 1</td>
<td>all_fields=1</td>
<td>Each matching search result is given as either an ID (0) or the full resource record.</td>
</tr>
<tr>
<td>offset, limit</td>
<td>result-int (defaults: offset=0, limit=20)</td>
<td>offset=40&amp;limit=20</td>
<td>Pagination options. Offset is the number of the first result and limit is the number of results to return.</td>
</tr>
</tbody>
</table>

Note: Powerful searching from the command-line can be achieved with curl and the qjson parameter. In this case you need to remember to escape the curly braces and use url encoding (e.g. spaces become %20). For example:

Revision Parameters

<table>
<thead>
<tr>
<th>Param-Key</th>
<th>Param-Value</th>
<th>Example</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>since_time</td>
<td>Date-Time</td>
<td>since_time=2010-05-05T19:42:45.854533</td>
<td>The time can be less precisely stated (e.g 2010-05-05).</td>
</tr>
<tr>
<td>since_id</td>
<td>Uuid</td>
<td>since_id=6e9f32ef-1f93-4b2f-891b-fd01924ebe08</td>
<td>The stated id will not be included in the results.</td>
</tr>
</tbody>
</table>
4.1.2 Util API

The Util API provides various utility APIs – e.g. auto-completion APIs used by front-end javascript.
All Util APIs are read-only. The response format is JSON. Javascript calls may want to use the JSONP formatting.

**dataset autocomplete**

There an autocomplete API for package names which matches on name or title.

This URL:

```
/api/2/util/dataset/autocomplete?incomplete=a%20novel
```

Returns:

```
{"ResultSet": [{"match_field": "title", "match_displayed": "A Novel By Tolstoy (annakarenina)", "name": "annakarenina", "title": "A Novel By Tolstoy"]}}
```

**tag autocomplete**

There is also an autocomplete API for tags which looks like this:

This URL:

```
/api/2/util/tag/autocomplete?incomplete=ru
```

Returns:

```
{"ResultSet": [{"Name": "russian"]}
```

**resource format autocomplete**

Similarly, there is an autocomplete API for the resource format field which is available at:

```
/api/2/util/resource/format_autocomplete?incomplete=cs
```

This returns:

```
{"ResultSet": [{"Format": "csv"]}
```

**markdown**

Takes a raw markdown string and returns a corresponding chunk of HTML. CKAN uses the basic Mark-
down format with some modifications (for security) and useful additions (e.g. auto links to datasets etc. e.g. dataset:river-quality).

Example:

```
```

Returns:
is slug valid

Checks a name is valid for a new dataset (package) or group, with respect to it being used already.

Example:

/api/2/util/is_slug_valid?slug=river-quality&type=package

Response:

{"valid": true}

munge package name

For taking an readable identifier and munging it to ensure it is a valid dataset id. Symbols and whitespace are converted into dashes. Example:

/api/util/dataset/munge_name?name=police%20spending%20figures%202009

Returns:

"police-spending-figures-2009"

munge title to package name

For taking a title of a package and munging it to a readable and valid dataset id. Symbols and whitespace are converted into dashes, with multiple dashes collapsed. Ensures that long titles with a year at the end preserves the year should it need to be shortened. Example:

/api/util/dataset/munge_title_to_name?title=police:%20spending%20figures%202009

Returns:

"police-spending-figures-2009"

munge tag

For taking a readable word/phrase and munging it to a valid tag (name). Symbols and whitespace are converted into dashes. Example:

/api/util/tag/munge?tag=water%20quality

Returns:

"water-quality"
### 4.1.3 Status Codes

Standard HTTP status codes are used to signal method outcomes.

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>OK</td>
</tr>
<tr>
<td>201</td>
<td>OK and new object created (referred to in the Location header)</td>
</tr>
<tr>
<td>301</td>
<td>Moved Permanently</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request</td>
</tr>
<tr>
<td>403</td>
<td>Not Authorized</td>
</tr>
<tr>
<td>404</td>
<td>Not Found</td>
</tr>
<tr>
<td>409</td>
<td>Conflict (e.g. name already exists)</td>
</tr>
<tr>
<td>500</td>
<td>Service Error</td>
</tr>
</tbody>
</table>

**Note:** On early CKAN versions, datasets were called “packages” and this name has stuck in some places, specially internally and on API calls. Package has exactly the same meaning as “dataset”.

### 4.2 Making an API request

To call the CKAN API, post a JSON dictionary in an HTTP POST request to one of CKAN’s API URLs. The parameters for the API function should be given in the JSON dictionary. CKAN will also return its response in a JSON dictionary.

One way to post a JSON dictionary to a URL is using the command-line HTTP client HTTPie. For example, to get a list of the names of all the datasets in the `data-explorer` group on demo.ckan.org, install HTTPie and then call the `group_list` API function by running this command in a terminal:

```
http http://demo.ckan.org/api/3/action/group_list
```

The response from CKAN will look like this:

```
{
  "help": "...",
  "result": [
    "data-explorer",
    "department-of-ricky",
    "geo-examples",
    "geothermal-data",
    "reykjavik",
    "skeenawild-conservation-trust"
  ],
  "success": true
}
```

The response is a JSON dictionary with three keys:

1. "success": true or false.

   The API aims to always return 200 OK as the status code of its HTTP response, whether there were errors with the request or not, so it’s important to always check the value of the "success" key in the response dictionary and (if success is false) check the value of the "error" key.
Note: If there are major formatting problems with a request to the API, CKAN may still return an HTTP response with a 409, 400 or 500 status code (in increasing order of severity). In future CKAN versions we intend to remove these responses, and instead send a 200 OK response and use the "success" and "error" items.

2. "result": the returned result from the function you called. The type and value of the result depend on which function you called. In the case of the group_list function it’s a list of strings, the names of all the datasets that belong to the group.

If there was an error responding to your request, the dictionary will contain an "error" key with details of the error instead of the "result" key. A response dictionary containing an error will look like this:

```
{
    "help": "Creates a package",
    "success": false,
    "error": {
        "message": "Access denied",
        "__type": "Authorization Error"
    }
}
```

3. "help": the documentation string for the function you called.

The same HTTP request can be made using Python’s standard urllib2 module, with this Python code:

```
#!/usr/bin/env python
import urllib2
import urllib
import json
import pprint

# Make the HTTP request.
response = urllib2.urlopen('http://demo.ckan.org/api/3/action/group_list',
                          data_string)
assert response.code == 200

# Use the json module to load CKAN's response into a dictionary.
response_dict = json.loads(response.read())

# Check the contents of the response.
assert response_dict['success'] is True
result = response_dict['result']
pprint.pprint(result)
```

4.3 Example: Importing datasets with the CKAN API

You can add datasets using CKAN’s web interface, but when importing many datasets it’s usually more efficient to automate the process in some way. In this example, we’ll show you how to use the CKAN API to write a Python script to import datasets into CKAN.

Todo: Make this script more interesting (eg. read data from a CSV file), and all put the script in a .py file somewhere with tests and import it here.
#!/usr/bin/env python
import urllib2
import urllib
import json
import pprint

# Put the details of the dataset we're going to create into a dict.
dataset_dict = {
    'name': 'my_dataset_name',
    'notes': 'A long description of my dataset',
    'owner_org': 'org_id_or_name'
}

# Use the json module to dump the dictionary to a string for posting.
data_string = urllib.quote(json.dumps(dataset_dict))

# We'll use the package_create function to create a new dataset.
request = urllib2.Request('http://www.my_ckan_site.com/api/action/package_create')

# Creating a dataset requires an authorization header.
# Replace *** with your API key, from your user account on the CKAN site
# that you're creating the dataset on.
request.add_header('Authorization', '***')

# Make the HTTP request.
response = urllib2.urlopen(request, data_string)
assert response.code == 200

# Use the json module to load CKAN's response into a dictionary.
response_dict = json.loads(response.read())
assert response_dict['success']

# package_create returns the created package as its result.
created_package = response_dict['result']
pprint.pprint(created_package)

For more examples, see API Examples.

## 4.4 API versions

The CKAN APIs are versioned. If you make a request to an API URL without a version number, CKAN will choose the latest version of the API:

```
http://demo.ckan.org/api/action/package_list
```

Alternatively, you can specify the desired API version number in the URL that you request:

```
http://demo.ckan.org/api/3/action/package_list
```

Version 3 is currently the only version of the Action API.

We recommend that you specify the API number in your requests, because this ensures that your API client will work across different sites running different version of CKAN (and will keep working on the same sites, when those sites upgrade to new versions of CKAN). Because the latest version of the API may change when a site is upgraded to a new
version of CKAN, or may differ on different sites running different versions of CKAN, the result of an API request that doesn’t specify the API version number cannot be relied on.

4.5 Authentication and API keys

Some API functions require authorization. The API uses the same authorization functions and configuration as the web interface, so if a user is authorized to do something in the web interface they’ll be authorized to do it via the API as well.

When calling an API function that requires authorization, you must authenticate yourself by providing your API key with your HTTP request. To find your API key, login to the CKAN site using its web interface and visit your user profile page.

To provide your API key in an HTTP request, include it in either an Authorization or X-CKAN-API-Key header. (The name of the HTTP header can be configured with the apikey_header_name option in your CKAN configuration file.)

For example, to ask whether or not you’re currently following the user markw on demo.ckan.org using HTTPie, run this command:

```
http http://demo.ckan.org/api/3/action/am_following_user id=markw Authorization:XXX
```

(Replacing XXX with your API key.)

Or, to get the list of activities from your user dashboard on demo.ckan.org, run this Python code:

```
request = urllib2.Request('http://demo.ckan.org/api/3/action/dashboard_activity_list')
request.add_header('Authorization', 'XXX')
response_dict = json.loads(urllib2.urlopen(request, '{}').read())
```

4.6 GET-able API functions

Functions defined in ckan.logic.action.get can also be called with an HTTP GET request. For example, to get the list of datasets (packages) from demo.ckan.org, open this URL in your browser:

```
http://demo.ckan.org/api/3/action/package_list
```

Or, to search for datasets (packages) matching the search query spending, on demo.ckan.org, open this URL in your browser:

```
http://demo.ckan.org/api/3/action/package_search?q=spending
```

**Tip:** Browser plugins like JSONView for Firefox or Chrome will format and color CKAN’s JSON response nicely in your browser.

The search query is given as a URL parameter ?q=spending. Multiple URL parameters can be appended, separated by & characters, for example to get only the first 10 matching datasets open this URL:

```
http://demo.ckan.org/api/3/action/package_search?q=spending&rows=10
```

When an action requires a list of strings as the value of a parameter, the value can be sent by giving the parameter multiple times in the URL:

```
```
4.7 JSONP support

To cater for scripts from other sites that wish to access the API, the data can be returned in JSONP format, where the JSON data is ‘padded’ with a function call. The function is named in the ‘callback’ parameter. For example:

http://demo.ckan.org/api/3/action/package_show?id=adur_district_spending&callback=myfunction

Note: This only works for GET requests

4.8 API Examples

4.8.1 Tags (not in a vocabulary)

A list of all tags:

- browser:  http://demo.ckan.org/api/3/action/tag_list
- curl:  curl http://demo.ckan.org/api/3/action/tag_list
- ckanapi: ckanapi -r http://demo.ckan.org action tag_list

Top 10 tags used by datasets:

- browser:  http://demo.ckan.org/api/action/package_search?facet.field={"tags"}&facet.limit=10&rows=0
- curl:  curl 'http://demo.ckan.org/api/action/package_search?facet.field=\"tags\"&facet.limit=10&rows=0'
- ckanapi: ckanapi -r http://demo.ckan.org action package_search facet.field='\"tags\"' facet.limit=10 rows=0

All datasets that have tag ‘economy’:

- ckanapi: ckanapi -r http://demo.ckan.org action package_search fq='tags:economy'

4.8.2 Tag Vocabularies

Top 10 tags and vocabulary tags used by datasets:

- browser:  http://demo.ckan.org/api/action/package_search?facet.field={"tags"}&facet.limit=10&rows=0
- curl:  curl 'http://demo.ckan.org/api/action/package_search?facet.field=\"tags\"&facet.limit=10&rows=0'
- ckanapi: ckanapi -r http://demo.ckan.org action package_search facet.field='\"tags\"' facet.limit=10 rows=0
e.g. Facet: vocab_Topics means there is a vocabulary called Topics, and its top tags are listed under it.

A list of datasets using tag ‘education’ from vocabulary ‘Topics’:

- **browser:** https://data.hdx.rwlabs.org/api/3/action/package_search?fq=vocab_Topics:education
- **curl:** curl 'https://data.hdx.rwlabs.org/api/3/action/package_search?fq=vocab_Topics:education'
- **ckanapi:** ckanapi -r https://data.hdx.rwlabs.org action package_searchfq='vocab_Topics:education'

### 4.8.3 Uploading a new version of a resource file

You can use the `upload` parameter of the `resource_update()` function to upload a new version of a resource file. This requires a `multipart/form-data` request, with `httpie` you can do this using the `@file.csv`:

```bash
http --json POST http://demo.ckan.org/api/3/action/resource_update id=<resource id>– upload=@updated_file.csv Authorization:<api key>
```

### 4.9 Action API reference

**Note:** If you call one of the action functions listed below and the function raises an exception, the API will return a JSON dictionary with keys "success": false and and an "error" key indicating the exception that was raised.

For example `member_list()` (which returns a list of the members of a group) raises `NotFound` if the group doesn’t exist. If you called it over the API, you’d get back a JSON dict like this:

```json
{
    "success": false,
    "error": {
        "__type": "Not Found Error",
        "message": "Not found"
    },
    "help": "...",
}
```

#### 4.9.1 ckan.logic.action.get

API functions for searching for and getting data from CKAN.

- **ckan.logic.action.get**.site_read(context, data_dict=None)
  
  Return True.

  Return type  bool

- **ckan.logic.action.get**.package_list(context, data_dict)
  
  Return a list of the names of the site’s datasets (packages).

  Parameters
  
  - **limit (int)** – if given, the list of datasets will be broken into pages of at most limit datasets per page and only one page will be returned at a time (optional)
offset (int) – when limit is given, the offset to start returning packages from

Return type  list of strings

ckan.logic.action.get.current_package_list_with_resources (context, data_dict)
Return a list of the site’s datasets (packages) and their resources.

The list is sorted most-recently-modified first.

Parameters

• limit (int) – if given, the list of datasets will be broken into pages of at most limit datasets per page and only one page will be returned at a time (optional)

• offset (int) – when limit is given, the offset to start returning packages from

• page (int) – when limit is given, which page to return, Deprecated: use offset

Return type  list of dictionaries

ckan.logic.action.get.revision_list (context, data_dict)
Return a list of the IDs of the site’s revisions. They are sorted with the newest first.

Since the results are limited to 50 IDs, you can page through them using parameter since_id.

Parameters

• since_id (string) – the revision ID after which you want the revisions

• since_time (string) – the timestamp after which you want the revisions

• sort (string) – the order to sort the related items in, possible values are ‘time_asc’, ‘time_desc’ (default). (optional)

Return type  list of revision IDs, limited to 50

ckan.logic.action.get.package_revision_list (context, data_dict)
Return a dataset (package)'s revisions as a list of dictionaries.

Parameters

id (string) – the id or name of the dataset

ckan.logic.action.get.member_list (context, data_dict=None)
Return the members of a group.

The user must have permission to ‘get’ the group.

Parameters

• id (string) – the id or name of the group

• object_type (string) – restrict the members returned to those of a given type, e.g. 'user' or 'package' (optional, default: None)

• capacity (string) – restrict the members returned to those with a given capacity, e.g. 'member', 'editor', 'admin', 'public', 'private' (optional, default: None)

Return type  list of (id, type, capacity) tuples

Raises  ckan.logic.NotFound: if the group doesn’t exist

ckan.logic.action.get.group_list (context, data_dict)
Return a list of the names of the site’s groups.

Parameters

• order_by (string) – the field to sort the list by, must be 'name' or 'packages' (optional, default: 'name') Deprecated use sort.
**sort** (*string*) – sorting of the search results. Optional. Default: “name asc” string of field name and sort-order. The allowed fields are ‘name’, ‘package_count’ and ‘title’

**limit** (*int*) – if given, the list of groups will be broken into pages of at most limit groups per page and only one page will be returned at a time (optional)

**offset** (*int*) – when limit is given, the offset to start returning groups from

**groups** (*list of strings*) – a list of names of the groups to return, if given only groups whose names are in this list will be returned (optional)

**all_fields** (*bool*) – return group dictionaries instead of just names. Only core fields are returned - get some more using the include_* options. Returning a list of packages is too expensive, so the packages property for each group is deprecated, but there is a count of the packages in the package_count property. (optional, default: False)

**include_dataset_count** (*bool*) – if all_fields, include the full package_count (optional, default: True)

**include_extras** (*bool*) – if all_fields, include the group extra fields (optional, default: False)

**include_tags** (*bool*) – if all_fields, include the group tags (optional, default: False)

**include_groups** (*bool*) – if all_fields, include the groups the groups are in (optional, default: False).

**include_users** (*bool*) – if all_fields, include the group users (optional, default: False).

**Return type**  list of strings

*ckan.logic.action.get.organization_list*(context, data_dict)

Return a list of the names of the site’s organizations.

**Parameters**

**order_by** (*string*) – the field to sort the list by, must be 'name' or 'packages' (optional, default: 'name') Deprecated use sort.

**sort** (*string*) – sorting of the search results. Optional. Default: “name asc” string of field name and sort-order. The allowed fields are ‘name’, ‘package_count’ and ‘title’

**limit** (*int*) – if given, the list of organizations will be broken into pages of at most limit organizations per page and only one page will be returned at a time (optional)

**offset** (*int*) – when limit is given, the offset to start returning organizations from

**organizations** (*list of strings*) – a list of names of the groups to return, if given only groups whose names are in this list will be returned (optional)

**all_fields** (*bool*) – return group dictionaries instead of just names. Only core fields are returned - get some more using the include_* options. Returning a list of packages is too expensive, so the packages property for each group is deprecated, but there is a count of the packages in the package_count property. (optional, default: False)

**include_dataset_count** (*bool*) – if all_fields, include the full package_count (optional, default: True)

**include_extras** (*bool*) – if all_fields, include the organization extra fields (optional, default: False)

**include_tags** (*bool*) – if all_fields, include the organization tags (optional, default: False)
• **include_groups** (bool) – if all_fields, include the organizations the organizations are in (optional, default: False)

• **include_users** (bool) – if all_fields, include the organization users (optional, default: False).

**Return type** list of strings

**ckan.logic.action.get.group_list_authz**(context, data_dict)

Return the list of groups that the user is authorized to edit.

**Parameters**

• **available_only** (bool) – remove the existing groups in the package (optional, default: False)

• **am_member** (bool) – if True return only the groups the logged-in user is a member of, otherwise return all groups that the user is authorized to edit (for example, sysadmin users are authorized to edit all groups) (optional, default: False)

**Returns** list of dictized groups that the user is authorized to edit

**Return type** list of dicts

**ckan.logic.action.get.organization_list_for_user**(context, data_dict)

Return the organizations that the user has a given permission for.

Specifically it returns the list of organizations that the currently authorized user has a given permission (for example: “manage_group”) against.

By default this returns the list of organizations that the currently authorized user is member of, in any capacity.

When a user becomes a member of an organization in CKAN they’re given a “capacity” (sometimes called a “role”), for example “member”, “editor” or “admin”.

Each of these roles has certain permissions associated with it. For example the admin role has the “admin” permission (which means they have permission to do anything). The editor role has permissions like “create_dataset”, “update_dataset” and “delete_dataset”. The member role has the “read” permission.

This function returns the list of organizations that the authorized user has a given permission for. For example the list of organizations that the user is an admin of, or the list of organizations that the user can create datasets in. This takes account of when permissions cascade down an organization hierarchy.

**Parameters**

• **id** (string) – the name or id of the user to get the organization list for (optional, defaults to the currently authorized user (logged in or via API key))

• **permission** (string) – the permission the user has against the returned organizations, for example "read" or "create_dataset" (optional, default: "manage_group")

• **include_dataset_count** (bool) – include the package_count in each org (optional, default: False)

**Returns** list of organizations that the user has the given permission for

**Return type** list of dicts

**ckan.logic.action.get.group_revision_list**(context, data_dict)

Return a group’s revisions.

**Parameters**

**id** (string) – the name or id of the group

**Return type** list of dictionaries
ckan.logic.action.get.organization_revision_list(context, data_dict)
    Return an organization’s revisions.
    
    Parameters id (string) – the name or id of the organization
    
    Return type list of dictionaries

ckan.logic.action.get.license_list(context, data_dict)
    Return the list of licenses available for datasets on the site.
    
    Return type list of dictionaries

ckan.logic.action.get.tag_list(context, data_dict)
    Return a list of the site’s tags.
    
    By default only free tags (tags that don’t belong to a vocabulary) are returned. If the vocabulary_id argu-
    ment is given then only tags belonging to that vocabulary will be returned instead.
    
    Parameters
    
    • query (string) – a tag name query to search for, if given only tags whose names contain
      this string will be returned (optional)
    
    • vocabulary_id (string) – the id or name of a vocabulary, if give only tags that belong
      to this vocabulary will be returned (optional)
    
    • all_fields (bool) – return full tag dictionaries instead of just names (optional, default: False)
    
    Return type list of dictionaries

ckan.logic.action.get.user_list(context, data_dict)
    Return a list of the site’s user accounts.
    
    Parameters
    
    • q (string) – filter the users returned to those whose names contain a string (optional)
    
    • email (string) – filter the users returned to those whose email match a string (optional)
      (you must be a sysadmin to use this filter)
    
    • order_by (string) – which field to sort the list by (optional, default: 'display_name'). Users can be sorted by 'id', 'name',
      'fullname', 'display_name', 'created', 'about', 'sysadmin' or 'number_created_packages'.
    
    • all_fields (bool) – return full user dictionaries instead of just names. (optional, default: True)
    
    Return type list of user dictionaries. User properties include: number_of_edits which counts
    the revisions by the user and number_created_packages which excludes datasets which
    are private or draft state.

ckan.logic.action.get.package_relationships_list(context, data_dict)
    Return a dataset (package)’s relationships.
    
    Parameters
    
    • id (string) – the id or name of the first package
    
    • id2 (string) – the id or name of the second package
    
    • rel – relationship as string see package_relationship_create() for the relation-
      ship types (optional)
    
    Return type list of dictionaries
ckan.logic.action.get.package_show(context, data_dict)
Return the metadata of a dataset (package) and its resources.

Parameters

• id(string) – the id or name of the dataset

• use_default_schema (bool) – use default package schema instead of a custom
  schema defined with an IDatasetForm plugin (default: False)

• include_tracking (bool) – add tracking information to dataset and resources (de-
  fault: False)

Return type  dictionary

ckan.logic.action.get.resource_show(context, data_dict)
Return the metadata of a resource.

Parameters

• id(string) – the id of the resource

• include_tracking (bool) – add tracking information to dataset and resources (de-
  fault: False)

Return type  dictionary

ckan.logic.action.get.resource_view_show(context, data_dict)
Return the metadata of a resource_view.

Parameters  id(string) – the id of the resource_view

Return type  dictionary

ckan.logic.action.get.resource_view_list(context, data_dict)
Return the list of resource views for a particular resource.

Parameters  id(string) – the id of the resource

Return type  list of dictionaries.

ckan.logic.action.get.revision_show(context, data_dict)
Return the details of a revision.

Parameters  id(string) – the id of the revision

Return type  dictionary

ckan.logic.action.get.group_show(context, data_dict)
Return the details of a group.

Parameters

• id(string) – the id or name of the group

• include_datasets (bool) – include a truncated list of the group’s datasets (optional,
  default: False)

• include_dataset_count (bool) – include the full package_count (optional, default: True)

• include_extras (bool) – include the group’s extra fields (optional, default: True)

• include_users (bool) – include the group’s users (optional, default: True)

• include_groups (bool) – include the group’s sub groups (optional, default: True)

• include_tags (bool) – include the group’s tags (optional, default: True)
• **include_followers** *(bool)* – include the group’s number of followers (optional, default: True)

**Return type** dictionary

---

**Note:** Only its first 1000 datasets are returned

### ckan.logic.action.get.organization_show *(context, data_dict)*

Return the details of a organization.

**Parameters**

• **id** *(string)* – the id or name of the organization

• **include_datasets** *(bool)* – include a truncated list of the org’s datasets (optional, default: False)

• **include_dataset_count** *(bool)* – include the full package_count (optional, default: True)

• **include_extras** *(bool)* – include the organization’s extra fields (optional, default: True)

• **include_users** *(bool)* – include the organization’s users (optional, default: True)

• **include_groups** *(bool)* – include the organization’s sub groups (optional, default: True)

• **include_tags** *(bool)* – include the organization’s tags (optional, default: True)

• **include_followers** *(bool)* – include the organization’s number of followers (optional, default: True)

**Return type** dictionary

---

**Note:** Only its first 1000 datasets are returned

### ckan.logic.action.get.group_package_show *(context, data_dict)*

Return the datasets (packages) of a group.

**Parameters**

• **id** *(string)* – the id or name of the group

• **limit** *(int)* – the maximum number of datasets to return (optional)

**Return type** list of dictionaries

### ckan.logic.action.get.tag_show *(context, data_dict)*

Return the details of a tag and all its datasets.

**Parameters**

• **id** *(string)* – the name or id of the tag

• **vocabulary_id** *(string)* – the id or name of the tag vocabulary that the tag is in - if it is not specified it will assume it is a free tag. (optional)

• **include_datasets** *(bool)* – include a list of the tag’s datasets. (Up to a limit of 1000 - for more flexibility, use package_search - see `package_search()` for an example.) (optional, default: False)
**Returns** the details of the tag, including a list of all of the tag’s datasets and their details

**Return type** dictionary

`ckan.logic.action.get.user_show(context, data_dict)`

Return a user account.

Either the `id` or the `user_obj` parameter must be given.

**Parameters**

- **id** *(string)* – the id or name of the user (optional)
- **user_obj** *(user dictionary)* – the user dictionary of the user (optional)
- **include_datasets** *(bool)* – Include a list of datasets the user has created. If it is the same user or a sysadmin requesting, it includes datasets that are draft or private. (optional, default: False, limit:50)
- **include_num_followers** *(bool)* – Include the number of followers the user has (optional, default: False)
- **include_password_hash** *(bool)* – Include the stored password hash (sysadmin only, optional, default: False)

**Returns** the details of the user. Includes email_hash, number_of_edits and number_created_packages (which excludes draft or private datasets unless it is the same user or sysadmin making the request). Excludes the password (hash) and reset_key. If it is the same user or a sysadmin requesting, the email and apikey are included.

**Return type** dictionary

`ckan.logic.action.get.package_autocomplete(context, data_dict)`

Return a list of datasets (packages) that match a string.

Datasets with names or titles that contain the query string will be returned.

**Parameters**

- **q** *(string)* – the string to search for
- **limit** *(int)* – the maximum number of resource formats to return (optional, default: 10)

**Return type** list of dictionaries

`ckan.logic.action.get.format_autocomplete(context, data_dict)`

Return a list of resource formats whose names contain a string.

**Parameters**

- **q** *(string)* – the string to search for
- **limit** *(int)* – the maximum number of resource formats to return (optional, default: 5)

**Return type** list of strings

`ckan.logic.action.get.user_autocomplete(context, data_dict)`

Return a list of user names that contain a string.

**Parameters**

- **q** *(string)* – the string to search for
- **limit** *(int)* – the maximum number of user names to return (optional, default: 20)

**Return type** a list of user dictionaries each with keys 'name', 'fullname', and 'id'
ckan.logic.action.get.group_autocomplete(context, data_dict)
Return a list of group names that contain a string.

Parameters
- **q** (string) – the string to search for
- **limit** (int) – the maximum number of groups to return (optional, default: 20)

Return type a list of group dictionaries each with keys 'name', 'title', and 'id'

ckan.logic.action.get.organization_autocomplete(context, data_dict)
Return a list of organization names that contain a string.

Parameters
- **q** (string) – the string to search for
- **limit** (int) – the maximum number of organizations to return (optional, default: 20)

Return type a list of organization dictionaries each with keys 'name', 'title', and 'id'

ckan.logic.action.get.package_search(context, data_dict)
Searches for packages satisfying a given search criteria.

This action accepts solr search query parameters (details below), and returns a dictionary of results, including dictized datasets that match the search criteria, a search count and also facet information.

**Solr Parameters:**
For more in depth treatment of each parameter, please read the Solr Documentation.

This action accepts a *subset* of solr’s search query parameters:

Parameters
- **q** (string) – the solr query. Optional. Default: "*:*"
- **fq** (string) – any filter queries to apply. Note: +site_id:{ckan_site_id} is added to this string prior to the query being executed.
- **sort** (string) – sorting of the search results. Optional. Default: 'relevance asc, metadata_modified desc'. As per the solr documentation, this is a comma-separated string of field names and sort-orderings.
- **rows** (int) – the number of matching rows to return. There is a hard limit of 1000 datasets per query.
- **start** (int) – the offset in the complete result for where the set of returned datasets should begin.
- **facet** (string) – whether to enable faceted results. Default: True.
- **facet.mincount** (int) – the minimum counts for facet fields should be included in the results.
- **facet.limit** (int) – the maximum number of values the facet fields return. A negative value means unlimited. This can be set instance-wide with the search.facets.limit config option. Default is 50.
- **facet.field** (list of strings) – the fields to facet upon. Default empty. If empty, then the returned facet information is empty.
- **include_drafts** (bool) – if True, draft datasets will be included in the results. A user will only be returned their own draft datasets, and a sysadmin will be returned all draft datasets. Optional, the default is False.
• **include_private** *(bool)* – if True, private datasets will be included in the results. Only private datasets from the user’s organizations will be returned and sysadmins will be returned all private datasets. Optional, the default is False.

• **use_default_schema** *(bool)* – use default package schema instead of a custom schema defined with an IDatasetForm plugin (default: False)

The following advanced Solr parameters are supported as well. Note that some of these are only available on particular Solr versions. See Solr’s dismax and edismax documentation for further details on them:

- *qf*, *wt*, *bf*, *boost*, *tie*, *defType*, *mm*

Examples:

- `q=flood` datasets containing the word *flood*, *floods* or *flooding*
- `fq=tags:economy` datasets with the tag *economy*
- `facet.field="tags"` facet limit=10 rows=0 top 10 tags

Results:

The result of this action is a dict with the following keys:

**Return type** A dictionary with the following keys

**Parameters**

- **count** *(int)* – the number of results found. Note, this is the total number of results found, not the total number of results returned (which is affected by limit and row parameters used in the input).

- **results** *(list of dictized datasets.)* – ordered list of datasets matching the query, where the ordering defined by the sort parameter used in the query.

- **facets** *(DEPRECATED dict)* – DEPRECATED. Aggregated information about facet counts.

- **search_facets** *(nested dict of dicts.)* – aggregated information about facet counts. The outer dict is keyed by the facet field name (as used in the search query). Each entry of the outer dict is itself a dict, with a “title” key, and an “items” key. The “items” key’s value is a list of dicts, each with “count”, “display_name” and “name” entries. The display_name is a form of the name that can be used in titles.

An example result:

```json
{'count': 2,
 'results': [ { <snip> }, { <snip> } ],
 'search_facets': {'tags': {'items': [{'count': 1,
 'display_name': u'tolstoy',
 'name': u'tolstoy'},
 {'count': 2,
 'display_name': u'russian',
 'name': u'russian'}
 ]}
 }
```

**Limitations:**

The full solr query language is not exposed, including.

- **fl** The parameter that controls which fields are returned in the solr query. fl can be None or a list of result fields, such as [’id’, ‘extras_custom_field’]. if fl = None, datasets are returned as a list of full dictionary.
ckan.logic.action.get.resource_search(context, data_dict)

Searches for resources satisfying a given search criteria.

It returns a dictionary with 2 fields: count and results. The count field contains the total number of Resources found without the limit or query parameters having an effect. The results field is a list of dictized Resource objects.

The ‘query’ parameter is a required field. It is a string of the form {field}:{term} or a list of strings, each of the same form. Within each string, {field} is a field or extra field on the Resource domain object.

If {field} is "hash", then an attempt is made to match the {term} as a prefix of the Resource.hash field.

If {field} is an extra field, then an attempt is made to match against the extra fields stored against the Resource.

Note: The search is limited to search against extra fields declared in the config setting ckan.extra_resource_fields.

Note: Due to a Resource’s extra fields being stored as a json blob, the match is made against the json string representation. As such, false positives may occur:

If the search criteria is:

```
query = "field1:term1"
```

Then a json blob with the string representation of:

```
{"field1": "foo", "field2": "term1"}
```

will match the search criteria! This is a known short-coming of this approach.

All matches are made ignoring case; and apart from the "hash" field, a term matches if it is a substring of the field’s value.

Finally, when specifying more than one search criteria, the criteria are AND-ed together.

The order parameter is used to control the ordering of the results. Currently only ordering one field is available, and in ascending order only.

The fields parameter is deprecated as it is not compatible with calling this action with a GET request to the action API.

The context may contain a flag, search_query, which if True will make this action behave as if being used by the internal search api. ie - the results will not be dictized, and SearchErrors are thrown for bad search queries (rather than ValidationErrors).

Parameters

- **query** (string or list of strings of the form {field}:{term}) – The search criteria. See above for description.
- **fields** (dict of fields to search terms.) – Deprecated
- **order_by** (string) – A field on the Resource model that orders the results.
- **offset** (int) – Apply an offset to the query.
- **limit** (int) – Apply a limit to the query.

Returns A dictionary with a count field, and a results field.

Return type dict
ckan.logic.action.get.tag_search(context, data_dict)
Return a list of tags whose names contain a given string.

By default only free tags (tags that don’t belong to any vocabulary) are searched. If the vocabulary_id argument is given then only tags belonging to that vocabulary will be searched instead.

Parameters
• query(string or list of strings) – the string(s) to search for
• vocabulary_id(string) – the id or name of the tag vocabulary to search in (optional)
• fields(dictionary) – deprecated
• limit(int) – the maximum number of tags to return
• offset(int) – when limit is given, the offset to start returning tags from

Returns
A dictionary with the following keys:
'count' The number of tags in the result.
'results' The list of tags whose names contain the given string, a list of dictionaries.

Return type dictionary

ckan.logic.action.get.tag_autocomplete(context, data_dict)
Return a list of tag names that contain a given string.

By default only free tags (tags that don’t belong to any vocabulary) are searched. If the vocabulary_id argument is given then only tags belonging to that vocabulary will be searched instead.

Parameters
• query(string) – the string to search for
• vocabulary_id(string) – the id or name of the tag vocabulary to search in (optional)
• fields(dictionary) – deprecated
• limit(int) – the maximum number of tags to return
• offset(int) – when limit is given, the offset to start returning tags from

Return type list of strings

ckan.logic.action.get.task_status_show(context, data_dict)
Return a task status.

Either the id parameter or the entity_id, task_type and key parameters must be given.

Parameters
• id(string) – the id of the task status (optional)
• entity_id(string) – the entity_id of the task status (optional)
• task_type(string) – the task_type of the task status (optional)
• key(string) – the key of the task status (optional)

Return type dictionary

ckan.logic.action.get.term_translation_show(context, data_dict)
Return the translations for the given term(s) and language(s).

Parameters
• **terms** (list of strings) – the terms to search for translations of, e.g. 'Russian', 'romantic novel'

• **lang_codes** (list of language code strings) – the language codes of the languages to search for translations into, e.g. 'en', 'de' (optional, default is to search for translations into any language)

**Return type** a list of term translation dictionaries each with keys 'term' (the term searched for, in the source language), 'term_translation' (the translation of the term into the target language) and 'lang_code' (the language code of the target language)

**ckan.logic.action.get.get_site_user** *(context, data_dict)*

Return the ckan site user

**Parameters**

- **defer_commit** (bool) – by default (or if set to false) get_site_user will commit and clean up the current transaction. If set to true, caller is responsible for committing transaction after get_site_user is called. Leaving open connections can cause cli commands to hang! (optional, default: False)

**ckan.logic.action.get.status_show** *(context, data_dict)*

Return a dictionary with information about the site’s configuration.

**Return type** dictionary

**ckan.logic.action.get.vocabulary_list** *(context, data_dict)*

Return a list of all the site’s tag vocabularies.

**Return type** list of dictionaries

**ckan.logic.action.get.vocabulary_show** *(context, data_dict)*

Return a single tag vocabulary.

**Parameters**

- **id** (string) – the id or name of the vocabulary

**Returns** the vocabulary.

**Return type** dictionary

**ckan.logic.action.get.user_activity_list** *(context, data_dict)*

Return a user’s public activity stream.

You must be authorized to view the user’s profile.

**Parameters**

- **id** (string) – the id or name of the user

- **offset** (int) – where to start getting activity items from (optional, default: 0)

- **limit** (int) – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** list of dictionaries

**ckan.logic.action.get.package_activity_list** *(context, data_dict)*

Return a package’s activity stream.

You must be authorized to view the package.

**Parameters**

- **id** (string) – the id or name of the package

- **offset** (int) – where to start getting activity items from (optional, default: 0)
• **limit (int)** – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** list of dictionaries

```python
ckan.logic.action.get.group_activity_list(context, data_dict)
```

Return a group’s activity stream.

You must be authorized to view the group.

**Parameters**

- **id (string)** – the id or name of the group
- **offset (int)** – where to start getting activity items from (optional, default: 0)
- **limit (int)** – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** list of dictionaries

```python
ckan.logic.action.get.organization_activity_list(context, data_dict)
```

Return an organization’s activity stream.

**Parameters**

- **id (string)** – the id or name of the organization

**Return type** list of dictionaries

```python
ckan.logic.action.get.recently_changed_packages_activity_list(context, data_dict)
```

Return the activity stream of all recently added or changed packages.

**Parameters**

- **offset (int)** – where to start getting activity items from (optional, default: 0)
- **limit (int)** – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** list of dictionaries

```python
ckan.logic.action.get.activity_detail_list(context, data_dict)
```

Return an activity’s list of activity detail items.

**Parameters**

- **id (string)** – the id of the activity

**Return type** list of dictionaries

```python
ckan.logic.action.get.user_activity_list_html(context, data_dict)
```

Return a user’s public activity stream as HTML.

The activity stream is rendered as a snippet of HTML meant to be included in an HTML page, i.e. it doesn’t have any HTML header or footer.

**Parameters**

- **id (string)** – The id or name of the user.
- **offset (int)** – where to start getting activity items from (optional, default: 0)
- **limit (int)** – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** string
ckan.logic.action.get.package_activity_list_html(context, data_dict)
Return a package’s activity stream as HTML.

The activity stream is rendered as a snippet of HTML meant to be included in an HTML page, i.e. it doesn’t have any HTML header or footer.

**Parameters**

- id *(string)* – the id or name of the package
- offset *(int)* – where to start getting activity items from (optional, default: 0)
- limit *(int)* – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** string

ckan.logic.action.get.group_activity_list_html(context, data_dict)
Return a group’s activity stream as HTML.

The activity stream is rendered as a snippet of HTML meant to be included in an HTML page, i.e. it doesn’t have any HTML header or footer.

**Parameters**

- id *(string)* – the id or name of the group
- offset *(int)* – where to start getting activity items from (optional, default: 0)
- limit *(int)* – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** string

ckan.logic.action.get.organization_activity_list_html(context, data_dict)
Return a organization’s activity stream as HTML.

The activity stream is rendered as a snippet of HTML meant to be included in an HTML page, i.e. it doesn’t have any HTML header or footer.

**Parameters** id *(string)* – the id or name of the organization

**Return type** string

ckan.logic.action.get.recently_changed_packages_activity_list_html(context, data_dict)
Return the activity stream of all recently changed packages as HTML.

The activity stream includes all recently added or changed packages. It is rendered as a snippet of HTML meant to be included in an HTML page, i.e. it doesn’t have any HTML header or footer.

**Parameters**

- offset *(int)* – where to start getting activity items from (optional, default: 0)
- limit *(int)* – the maximum number of activities to return (optional, default: 31, the default value is configurable via the ckan.activity_list_limit setting)

**Return type** string

ckan.logic.action.get.user_follower_count(context, data_dict)
Return the number of followers of a user.

**Parameters** id *(string)* – the id or name of the user

**Return type** int
ckan.logic.action.get.dataset_follower_count(context, data_dict)
Return the number of followers of a dataset.

Parameters id (string) – the id or name of the dataset
Return type int

ckan.logic.action.get.group_follower_count(context, data_dict)
Return the number of followers of a group.

Parameters id (string) – the id or name of the group
Return type int

ckan.logic.action.get.organization_follower_count(context, data_dict)
Return the number of followers of an organization.

Parameters id (string) – the id or name of the organization
Return type int

ckan.logic.action.get.user_follower_list(context, data_dict)
Return the list of users that are following the given user.

Parameters id (string) – the id or name of the user
Return type list of dictionaries

ckan.logic.action.get.dataset_follower_list(context, data_dict)
Return the list of users that are following the given dataset.

Parameters id (string) – the id or name of the dataset
Return type list of dictionaries

ckan.logic.action.get.group_follower_list(context, data_dict)
Return the list of users that are following the given group.

Parameters id (string) – the id or name of the group
Return type list of dictionaries

ckan.logic.action.get.organization_follower_list(context, data_dict)
Return the list of users that are following the given organization.

Parameters id (string) – the id or name of the organization
Return type list of dictionaries

ckan.logic.action.get.am_following_user(context, data_dict)
Return True if you’re following the given user, False if not.

Parameters id (string) – the id or name of the user
Return type bool

ckan.logic.action.get.am_following_dataset(context, data_dict)
Return True if you’re following the given dataset, False if not.

Parameters id (string) – the id or name of the dataset
Return type bool

ckan.logic.action.get.am_following_group(context, data_dict)
Return True if you’re following the given group, False if not.

Parameters id (string) – the id or name of the group
Return type bool

ckan.logic.action.get.\texttt{followee\_count} (context, data\_dict)
Return the number of objects that are followed by the given user.

Counts all objects, of any type, that the given user is following (e.g. followed users, followed datasets, followed groups).

Parameters \texttt{id} (string) – the id of the user

Return type int

ckan.logic.action.get.\texttt{user\_followee\_count} (context, data\_dict)
Return the number of users that are followed by the given user.

Parameters \texttt{id} (string) – the id of the user

Return type int

ckan.logic.action.get.\texttt{dataset\_followee\_count} (context, data\_dict)
Return the number of datasets that are followed by the given user.

Parameters \texttt{id} (string) – the id of the user

Return type int

ckan.logic.action.get.\texttt{group\_followee\_count} (context, data\_dict)
Return the number of groups that are followed by the given user.

Parameters \texttt{id} (string) – the id of the user

Return type int

ckan.logic.action.get.\texttt{followee\_list} (context, data\_dict)
Return the list of objects that are followed by the given user.

Returns all objects, of any type, that the given user is following (e.g. followed users, followed datasets, followed groups.. ).

Parameters

• \texttt{id} (string) – the id of the user

• \texttt{q} (string) – a query string to limit results by, only objects whose display name begins with the given string (case-insensitive) will be returned (optional)

Return type list of dictionaries, each with keys 'type' (e.g. 'user', 'dataset' or 'group'), 'display\_name' (e.g. a user's display name, or a package's title) and 'dict' (e.g. a dict representing the followed user, package or group, the same as the dict that would be returned by \texttt{user\_show()}, \texttt{package\_show()} or \texttt{group\_show()})

ckan.logic.action.get.\texttt{user\_followee\_list} (context, data\_dict)
Return the list of users that are followed by the given user.

Parameters \texttt{id} (string) – the id of the user

Return type list of dictionaries

ckan.logic.action.get.\texttt{dataset\_followee\_list} (context, data\_dict)
Return the list of datasets that are followed by the given user.

Parameters \texttt{id} (string) – the id or name of the user

Return type list of dictionaries

ckan.logic.action.get.\texttt{group\_followee\_list} (context, data\_dict)
Return the list of groups that are followed by the given user.
Parameters **id** (*string*) – the id or name of the user

Return type  list of dictionaries

`ckan.logic.action.get.organization_followee_list (context, data_dict)`

Return the list of organizations that are followed by the given user.

Parameters **id** (*string*) – the id or name of the user

Return type  list of dictionaries

`ckan.logic.action.get.dashboard_activity_list (context, data_dict)`

Return the authorized (via login or API key) user’s dashboard activity stream.

Unlike the activity dictionaries returned by other \_\_activity_list actions, these activity dictionaries have an extra boolean value with key `is_new` that tells you whether the activity happened since the user last viewed her dashboard (`'is_new': True`) or not (`'is_new': False`).

The user’s own activities are always marked `'is_new': False`.

Parameters

- **offset** (*int*) – where to start getting activity items from (optional, default: 0)
- **limit** (*int*) – the maximum number of activities to return (optional, default: 31, the default value is configurable via the `ckan.activity_list_limit` setting)

Return type  list of activity dictionaries

`ckan.logic.action.get.dashboard_activity_list_html (context, data_dict)`

Return the authorized (via login or API key) user’s dashboard activity stream as HTML.

The activity stream is rendered as a snippet of HTML meant to be included in an HTML page, i.e. it doesn’t have any HTML header or footer.

Parameters

- **offset** (*int*) – where to start getting activity items from (optional, default: 0)
- **limit** (*int*) – the maximum number of activities to return (optional, default: 31, the default value is configurable via the `ckan.activity_list_limit` setting)

Return type  string

`ckan.logic.action.get.dashboard_new_activities_count (context, data_dict)`

Return the number of new activities in the user’s dashboard.

Return the number of new activities in the authorized user’s dashboard activity stream.

Activities from the user herself are not counted by this function even though they appear in the dashboard (users don’t want to be notified about things they did themselves).

Return type  int

`ckan.logic.action.get.member_roles_list (context, data_dict)`

Return the possible roles for members of groups and organizations.

Parameters **group_type** (*string*) – the group type, either "group" or "organization" (optional, default "organization")

Returns a list of dictionaries each with two keys: "text" (the display name of the role, e.g. "Admin") and "value" (the internal name of the role, e.g. "admin")

Return type  list of dictionaries
ckan.logic.action.get.$\texttt{help}\_\texttt{show}$(context, data\_dict)$

Return the help string for a particular API action.

**Parameters** name $\texttt{(string)}$ – Action function name (eg user\_create, package\_search)

**Returns** The help string for the action function, or None if the function does not have a docstring.

**Return type** string

**Raises** ckan.logic.NotFound: if the action function doesn’t exist

ckan.logic.action.get.$\texttt{config}\_\texttt{option}\_\texttt{show}$(context, data\_dict)$

Show the current value of a particular configuration option.

Only returns runtime-editable config options (the ones returned by $\texttt{config}\_\texttt{option}\_\texttt{list}()$), which can be updated with the $\texttt{config}\_\texttt{option}\_\texttt{update}()$ action.

**Parameters** key $\texttt{(string)}$ – The configuration option key

**Returns** The value of the config option from either the system\_info table or ini file.

**Return type** string

**Raises** ckan.logic.ValidationError: if config option is not in the schema (whitelisted as editable).

ckan.logic.action.get.$\texttt{config}\_\texttt{option}\_\texttt{list}$(context, data\_dict)$

Return a list of runtime-editable config options keys that can be updated with $\texttt{config}\_\texttt{option}\_\texttt{update}()$.

**Returns** A list of config option keys.

**Return type** list

ckan.logic.action.get.$\texttt{job}\_\texttt{list}$(context, data\_dict)$

List enqueued background jobs.

**Parameters** queues $\texttt{(list)}$ – Queues to list jobs from. If not given then the jobs from all queues are listed.

**Returns** The currently enqueued background jobs.

**Return type** list

New in version 2.7.

ckan.logic.action.get.$\texttt{job}\_\texttt{show}$(context, data\_dict)$

Show details for a background job.

**Parameters** id $\texttt{(string)}$ – The ID of the background job.

**Returns** Details about the background job.

**Return type** dict

New in version 2.7.

**4.9.2 ckan.logic.action.create**

API functions for adding data to CKAN.
ckan.logic.action.create.package_create(context, data_dict)

Create a new dataset (package).

You must be authorized to create new datasets. If you specify any groups for the new dataset, you must also be authorized to edit these groups.

Plugins may change the parameters of this function depending on the value of the type parameter, see the IDatasetForm plugin interface.

Parameters

- **name** (string) – the name of the new dataset, must be between 2 and 100 characters long and contain only lowercase alphanumeric characters, - and _, e.g. 'warandpeace'
- **title** (string) – the title of the dataset (optional, default: same as name)
- **private** (bool) – If True creates a private dataset
- **author** (string) – the name of the dataset’s author (optional)
- **author_email** (string) – the email address of the dataset’s author (optional)
- **maintainer** (string) – the name of the dataset’s maintainer (optional)
- **maintainer_email** (string) – the email address of the dataset’s maintainer (optional)
- **license_id** (license id string) – the id of the dataset’s license, see license_list() for available values (optional)
- **notes** (string) – a description of the dataset (optional)
- **url** (string) – a URL for the dataset’s source (optional)
- **version** (string, no longer than 100 characters) – (optional)
- **state** (string) – the current state of the dataset, e.g. 'active' or 'deleted', only active datasets show up in search results and other lists of datasets, this parameter will be ignored if you are not authorized to change the state of the dataset (optional, default: 'active')
- **type** (string) – the type of the dataset (optional), IDatasetForm plugins associate themselves with different dataset types and provide custom dataset handling behaviour for these types
- **resources** (list of resource dictionaries) – the dataset’s resources, see resource_create() for the format of resource dictionaries (optional)
- **tags** (list of tag dictionaries) – the dataset’s tags, see tag_create() for the format of tag dictionaries (optional)
- **extras** (list of dataset extra dictionaries) – the dataset’s extras (optional), extras are arbitrary (key: value) metadata items that can be added to datasets, each extra dictionary should have keys 'key' (a string), 'value' (a string)
- **relationships_as_object** (list of relationship dictionaries) – see package_relationship_create() for the format of relationship dictionaries (optional)
- **relationships_as_subject** (list of relationship dictionaries) – see package_relationship_create() for the format of relationship dictionaries (optional)
- **groups** (list of dictionaries) – the groups to which the dataset belongs (optional), each group dictionary should have one or more of the following keys which identify
an existing group: 'id' (the id of the group, string), or 'name' (the name of the group, string), to see which groups exist call group_list()

- **owner_org** (string) – the id of the dataset's owning organization, see organization_list() or organization_list_for_user() for available values. This parameter can be made optional if the config option ckan.auth.create_unowned_dataset is set to True.

**Returns** the newly created dataset (unless 'return_id_only' is set to True in the context, in which case just the dataset id will be returned)

**Return type** dictionary

```python
ckan.logic.action.create.resource_create(context, data_dict)
```

Appends a new resource to a datasets list of resources.

**Parameters**

- **package_id** (string) – id of package that the resource should be added to.
- **url** (string) – url of resource
- **revision_id** (string) – (optional)
- **description** (string) – (optional)
- **format** (string) – (optional)
- **hash** (string) – (optional)
- **name** (string) – (optional)
- **resource_type** (string) – (optional)
- **mimetype** (string) – (optional)
- **mimetype_inner** (string) – (optional)
- **cache_url** (string) – (optional)
- **size** (int) – (optional)
- **created** (iso date string) – (optional)
- **last_modified** (iso date string) – (optional)
- **cache_last_updated** (iso date string) – (optional)
- **upload** (FieldStorage (optional) needs multipart/form-data) – (optional)

**Returns** the newly created resource

**Return type** dictionary

```python
ckan.logic.action.create.resource_view_create(context, data_dict)
```

Creates a new resource view.

**Parameters**

- **resource_id** (string) – id of the resource
- **title** (string) – the title of the view
- **description** (string) – a description of the view (optional)
- **view_type** (string) – type of view
- **config** (JSON string) – options necessary to recreate a view state (optional)
Returns the newly created resource view

Return type dictionary

ckan.logic.action.create.resource_create_default_resource_views(context, data_dict)

Creates the default views (if necessary) on the provided resource

The function will get the plugins for the default views defined in the configuration, and if some were found the `can_view` method of each one of them will be called to determine if a resource view should be created. Resource views extensions get the resource dict and the parent dataset dict.

If the latter is not provided, `package_show` is called to get it.

By default only view plugins that don’t require the resource data to be in the DataStore are called. See `ckan.logic.action.create.package_create_default_resource_views` for details on the `create_datastore_views` parameter.

Parameters

- **resource (dict)** – full resource dict
- **package (dict)** – full dataset dict (optional, if not provided `package_show()` will be called).
- **create_datastore_views (bool)** – whether to create views that rely on data being on the DataStore (optional, defaults to False)

Returns a list of resource views created (empty if none were created)

Return type list of dictionaries

ckan.logic.action.create.package_create_default_resource_views(context, data_dict)

Creates the default views on all resources of the provided dataset

By default only view plugins that don’t require the resource data to be in the DataStore are called. Passing `create_datastore_views` as True will only create views that require data to be in the DataStore. The first case happens when the function is called from `package_create` or `package_update`, the second when it’s called from the DataPusher when data was uploaded to the DataStore.

Parameters

- **package (dict)** – full dataset dict (ie the one obtained calling `package_show()`).
- **create_datastore_views (bool)** – whether to create views that rely on data being on the DataStore (optional, defaults to False)

Returns a list of resource views created (empty if none were created)

Return type list of dictionaries

ckan.logic.action.create.package_relationship_create(context, data_dict)

Create a relationship between two datasets (packages).

You must be authorized to edit both the subject and the object datasets.

Parameters

- **subject (string)** – the id or name of the dataset that is the subject of the relationship
- **object** – the id or name of the dataset that is the object of the relationship
- **type (string)** – the type of the relationship, one of 'depends_on', 'dependency_of', 'derives_from', 'has_derivation', 'links_to', 'linked_from', 'child_of' or 'parent_of'
ckan.logic.action.create.member_create(context, data_dict=None)

Make an object (e.g. a user, dataset or group) a member of a group.

If the object is already a member of the group then the capacity of the membership will be updated.

You must be authorized to edit the group.

Parameters

- **id** (string) – the id or name of the group to add the object to
- **object** (string) – the id or name of the object to add
- **object_type** (string) – the type of the object being added, e.g. 'package' or 'user'
- **capacity** (string) – the capacity of the membership

Returns the newly created (or updated) membership

Return type dictionary

ckan.logic.action.create.group_create(context, data_dict)

Create a new group.

You must be authorized to create groups.

Plugins may change the parameters of this function depending on the value of the **type** parameter, see the **IGroupForm** plugin interface.

Parameters

- **name** (string) – the name of the group, a string between 2 and 100 characters long, containing only lowercase alphanumeric characters, – and _
- **id** (string) – the id of the group (optional)
- **title** (string) – the title of the group (optional)
- **description** (string) – the description of the group (optional)
- **image_url** (string) – the URL to an image to be displayed on the group’s page (optional)
- **type** (string) – the type of the group (optional), **IGroupForm** plugins associate themselves with different group types and provide custom group handling behaviour for these types Cannot be ‘organization’
- **state** (string) – the current state of the group, e.g. 'active' or 'deleted'. only active groups show up in search results and other lists of groups, this parameter will be ignored if you are not authorized to change the state of the group (optional, default: 'active')
- **approval_status** (string) – (optional)
- **extras** (list of dataset extra dictionaries) – the group’s extras (optional), extras are arbitrary (key: value) metadata items that can be added to groups, each extra dictionary should have keys 'key' (a string), 'value' (a string), and optionally 'deleted'
• **packages** *(list of dictionaries)* – the datasets (packages) that belong to the group, a list of dictionaries each with keys 'name' (string, the id or name of the dataset) and optionally 'title' (string, the title of the dataset)

• **groups** *(list of dictionaries)* – the groups that belong to the group, a list of dictionaries each with key 'name' (string, the id or name of the group) and optionally 'capacity' (string, the capacity in which the group is a member of the group)

• **users** *(list of dictionaries)* – the users that belong to the group, a list of dictionaries each with key 'name' (string, the id or name of the user) and optionally 'capacity' (string, the capacity in which the user is a member of the group)

**Returns** the newly created group (unless 'return_id_only' is set to True in the context, in which case just the group id will be returned)

**Return type** dictionary

```python
ckan.logic.action.create.organization_create(context, data_dict)
```

Create a new organization.

You must be authorized to create organizations.

Plugins may change the parameters of this function depending on the value of the type parameter, see the **IGroupForm** plugin interface.

**Parameters**

• **name** *(string)* – the name of the organization, a string between 2 and 100 characters long, containing only lowercase alphanumeric characters, - and _

• **id** *(string)* – the id of the organization (optional)

• **title** *(string)* – the title of the organization (optional)

• **description** *(string)* – the description of the organization (optional)

• **image_url** *(string)* – the URL to an image to be displayed on the organization’s page (optional)

• **state** *(string)* – the current state of the organization, e.g. 'active' or 'deleted', only active organizations show up in search results and other lists of organizations, this parameter will be ignored if you are not authorized to change the state of the organization (optional, default: 'active')

• **approval_status** *(string)* – (optional)

• **extras** *(list of dataset extra dictionaries)* – the organization’s extras (optional), extras are arbitrary (key: value) metadata items that can be added to organizations, each extra dictionary should have keys 'key' (a string), 'value' (a string), and optionally 'deleted'

• **packages** *(list of dictionaries)* – the datasets (packages) that belong to the organization, a list of dictionaries each with keys 'name' (string, the id or name of the dataset) and optionally 'title' (string, the title of the dataset)

• **users** *(list of dictionaries)* – the users that belong to the organization, a list of dictionaries each with key 'name' (string, the id or name of the user) and optionally 'capacity' (string, the capacity in which the user is a member of the organization)

**Returns** the newly created organization (unless 'return_id_only' is set to True in the context, in which case just the organization id will be returned)

**Return type** dictionary
ckan.logic.action.create.rating_create(context, data_dict)
Rate a dataset (package).

You must provide your API key in the Authorization header.

Parameters

• **package**(string) – the name or id of the dataset to rate

• **rating**(int) – the rating to give to the dataset, an integer between 1 and 5

Returns a dictionary with two keys: 'rating average' (the average rating of the dataset you rated) and 'rating count' (the number of times the dataset has been rated)

Return type dictionary

ckan.logic.action.create.user_create(context, data_dict)
Create a new user.

You must be authorized to create users.

Parameters

• **name**(string) – the name of the new user, a string between 2 and 100 characters in length, containing only lowercase alphanumeric characters, _ and 

• **email**(string) – the email address for the new user

• **password**(string) – the password of the new user, a string of at least 4 characters

• **id**(string) – the id of the new user (optional)

• **fullname**(string) – the full name of the new user (optional)

• **about**(string) – a description of the new user (optional)

Returns the newly created user

Return type dictionary

ckan.logic.action.create.user_invite(context, data_dict)
Invite a new user.

You must be authorized to create group members.

Parameters

• **email**(string) – the email of the user to be invited to the group

• **group_id**(string) – the id or name of the group

• **role**(string) – role of the user in the group. One of member, editor, or admin

Returns the newly created user

Return type dictionary

ckan.logic.action.create.vocabulary_create(context, data_dict)
Create a new tag vocabulary.

You must be a sysadmin to create vocabularies.

Parameters

• **name**(string) – the name of the new vocabulary, e.g. 'Genre'

• **tags**(list of tag dictionaries) – the new tags to add to the new vocabulary, for the format of tag dictionaries see tag_create()
Returns the newly-created vocabulary

Return type dictionary

ckan.logic.action.create.activity_create(context, activity_dict, **kw)
Create a new activity stream activity.
You must be a sysadmin to create new activities.

Parameters

• user_id (string) – the name or id of the user who carried out the activity, e.g. 'seanh'

• object_id – the name or id of the object of the activity, e.g. 'my_dataset'

• activity_type (string) – the type of the activity, this must be an activity type that CKAN knows how to render, e.g. 'new package', 'changed user', 'deleted group' etc.

• data (dictionary) – any additional data about the activity

Returns the newly created activity

Return type dictionary

ckan.logic.action.create.tag_create(context, data_dict)
Create a new vocabulary tag.
You must be a sysadmin to create vocabulary tags.
You can only use this function to create tags that belong to a vocabulary, not to create free tags. (To create a new free tag simply add the tag to a package, e.g. using the package_update() function.)

Parameters

• name (string) – the name for the new tag, a string between 2 and 100 characters long containing only alphanumeric characters and -_. and ., e.g. 'Jazz'

• vocabulary_id (string) – the id of the vocabulary that the new tag should be added to, e.g. the id of vocabulary 'Genre'

Returns the newly-created tag

Return type dictionary

ckan.logic.action.create.follow_user(context, data_dict)
Start following another user.
You must provide your API key in the Authorization header.

Parameters id (string) – the id or name of the user to follow, e.g. 'joeuser'

Returns a representation of the ‘follower’ relationship between yourself and the other user

Return type dictionary

ckan.logic.action.create.follow_dataset(context, data_dict)
Start following a dataset.
You must provide your API key in the Authorization header.

Parameters id (string) – the id or name of the dataset to follow, e.g. 'warandpeace'

Returns a representation of the ‘follower’ relationship between yourself and the dataset

Return type dictionary
ckan.logic.action.create.group_member_create(context, data_dict)
Make a user a member of a group.

You must be authorized to edit the group.

Parameters

• id (string) – the id or name of the group
• username (string) – name or id of the user to be made member of the group
• role (string) – role of the user in the group. One of member, editor, or admin

Returns the newly created (or updated) membership

Return type dictionary

ckan.logic.action.create.organization_member_create(context, data_dict)
Make a user a member of an organization.

You must be authorized to edit the organization.

Parameters

• id (string) – the id or name of the organization
• username (string) – name or id of the user to be made member of the organization
• role (string) – role of the user in the organization. One of member, editor, or admin

Returns the newly created (or updated) membership

Return type dictionary

ckan.logic.action.create.follow_group(context, data_dict)
Start following a group.

You must provide your API key in the Authorization header.

Parameters id (string) – the id or name of the group to follow, e.g. 'roger'

Returns a representation of the ‘follower’ relationship between yourself and the group

Return type dictionary

4.9.3 ckan.logic.action.update

API functions for updating existing data in CKAN.

ckan.logic.action.update.resource_update(context, data_dict)
Update a resource.

To update a resource you must be authorized to update the dataset that the resource belongs to.

For further parameters see resource_create().

Parameters id (string) – the id of the resource to update

Returns the updated resource

Return type string

ckan.logic.action.update.resource_view_update(context, data_dict)
Update a resource view.

To update a resource_view you must be authorized to update the resource that the resource_view belongs to.
For further parameters see `resource_view_create()`.

**Parameters**
- **id** *(string)* – the id of the resource_view to update
- **Returns** the updated resource_view
- **Return type** string

`ckan.logic.action.update.resource_view_reorder(context, data_dict)`
Reorder resource views.

**Parameters**
- **id** *(string)* – the id of the resource
- **order** *(list of strings)* – the list of id of the resource to update the order of the views
- **Returns** the updated order of the view
- **Return type** dictionary

`ckan.logic.action.update.package_update(context, data_dict)`
Update a dataset (package).

You must be authorized to edit the dataset and the groups that it belongs to.

It is recommended to call `ckan.logic.action.get.package_show()`, make the desired changes to the result, and then call `package_update()` with it.

Plugins may change the parameters of this function depending on the value of the dataset’s `type` attribute, see the `IDatasetForm` plugin interface.

For further parameters see `package_create()`.

**Parameters**
- **id** *(string)* – the name or id of the dataset to update
- **Returns** the updated dataset (if 'return_package_dict' is True in the context, which is the default. Otherwise returns just the dataset id)
- **Return type** dictionary

`ckan.logic.action.update.package_resource_reorder(context, data_dict)`
Reorder resources against datasets. If only partial resource ids are supplied then these are assumed to be first and the other resources will stay in their original order

**Parameters**
- **id** *(string)* – the id or name of the package to update
- **order** *(list)* – a list of resource ids in the order needed

`ckan.logic.action.update.package_relationship_update(context, data_dict)`
Update a relationship between two datasets (packages).

The subject, object and type parameters are required to identify the relationship. Only the comment can be updated.

You must be authorized to edit both the subject and the object datasets.

**Parameters**
- **subject** *(string)* – the name or id of the dataset that is the subject of the relationship
- **object** *(string)* – the name or id of the dataset that is the object of the relationship
• **type** (*string*) – the type of the relationship, one of 'depends_on', 'dependency_of', 'derives_from', 'hasDerivation', 'links_to', 'linked_from', 'child_of' or 'parent_of'

• **comment** (*string*) – a comment about the relationship (optional)

**Returns** the updated relationship

**Return type** *dictionary*

`ckan.logic.action.update.group_update(context, data_dict)`

Update a group.

You must be authorized to edit the group.

Plugins may change the parameters of this function depending on the value of the group’s **type** attribute, see the `IGroupForm` plugin interface.

For further parameters see `group_create()`.

**Parameters**

- **id** (*string*) – the name or id of the group to update

**Returns** the updated group

**Return type** *dictionary*

`ckan.logic.action.update.organization_update(context, data_dict)`

Update an organization.

You must be authorized to edit the organization.

For further parameters see `organization_create()`.

**Parameters**

- **id** (*string*) – the name or id of the organization to update

- **packages** – ignored. use `package_owner_org_update()` to change package ownership

**Returns** the updated organization

**Return type** *dictionary*

`ckan.logic.action.update.user_update(context, data_dict)`

Update a user account.

Normal users can only update their own user accounts. Sysadmins can update any user account. Can not modify existing user’s name.

For further parameters see `user_create()`.

**Parameters**

- **id** (*string*) – the name or id of the user to update

**Returns** the updated user account

**Return type** *dictionary*

`ckan.logic.action.update.user_generate_apikey(context, data_dict)`

Cycle a user’s API key

**Parameters**

- **id** (*string*) – the name or id of the user whose key needs to be updated

**Returns** the updated user

**Return type** *dictionary*
ckan.logic.action.update.task_status_update(context, data_dict)

Update a task status.

**Parameters**

- `id` *(string)* – the id of the task status to update
- `entity_id` *(string)* –
- `entity_type` *(string)* –
- `task_type` *(string)* –
- `key` *(string)* –
- `value` – (optional)
- `state` – (optional)
- `last_updated` – (optional)
- `error` – (optional)

**Returns** the updated task status

**Return type** dictionary

ckan.logic.action.update.task_status_update_many(context, data_dict)

Update many task statuses at once.

**Parameters**

- `data` *(list of dictionaries)* – the task_status dictionaries to update, for the format of task status dictionaries see *task_status_update()*

**Returns** the updated task statuses

**Return type** list of dictionaries

ckan.logic.action.update.term_translation_update(context, data_dict)

Create or update a term translation.

You must be a sysadmin to create or update term translations.

**Parameters**

- `term` *(string)* – the term to be translated, in the original language, e.g. 'romantic novel'
- `term_translation` *(string)* – the translation of the term, e.g. 'Liebesroman'
- `lang_code` *(string)* – the language code of the translation, e.g. 'de'

**Returns** the newly created or updated term translation

**Return type** dictionary

ckan.logic.action.update.term_translation_update_many(context, data_dict)

Create or update many term translations at once.

**Parameters**

- `data` *(list of dictionaries)* – the term translation dictionaries to create or update, for the format of term translation dictionaries see *term_translation_update()*

**Returns** a dictionary with key `success` whose value is a string stating how many term translations were updated

**Return type** string
**ckan.logic.action.update.vocabulary_update** *(context, data_dict)*

Update a tag vocabulary.

You must be a sysadmin to update vocabularies.

For further parameters see *vocabulary_create()*.

**Parameters**

- **id** *(string)* – the id of the vocabulary to update

**Returns** the updated vocabulary

**Return type** dictionary

**ckan.logic.action.update.dashboard_mark_activities_old** *(context, data_dict)*

Mark all the authorized user’s new dashboard activities as old.

This will reset *dashboard_new_activities_count()* to 0.

**ckan.logic.action.update.send_email_notifications** *(context, data_dict)*

Send any pending activity stream notification emails to users.

You must provide a sysadmin’s API key in the Authorization header of the request, or call this action from the

command-line via a *paster post* … command.

**ckan.logic.action.update.package_owner_org_update** *(context, data_dict)*

Update the owning organization of a dataset

**Parameters**

- **id** *(string)* – the name or id of the dataset to update
- **organization_id** *(string)* – the name or id of the owning organization

**ckan.logic.action.update.bulk_update_private** *(context, data_dict)*

Make a list of datasets private

**Parameters**

- **datasets** *(list of strings)* – list of ids of the datasets to update
- **org_id** *(int)* – id of the owning organization

**ckan.logic.action.update.bulk_update_public** *(context, data_dict)*

Make a list of datasets public

**Parameters**

- **datasets** *(list of strings)* – list of ids of the datasets to update
- **org_id** *(int)* – id of the owning organization

**ckan.logic.action.update.bulk_update_delete** *(context, data_dict)*

Make a list of datasets deleted

**Parameters**

- **datasets** *(list of strings)* – list of ids of the datasets to update
- **org_id** *(int)* – id of the owning organization

**ckan.logic.action.update.config_option_update** *(context, data_dict)*

New in version 2.4.

Allows to modify some CKAN runtime-editable config options

It takes arbitrary key, value pairs and checks the keys against the config options update schema. If some of the

provided keys are not present in the schema a *ValidationError* is raised. The values are then validated

against the schema, and if validation is passed, for each key, value config option:
• It is stored on the system_info database table
• The Pylons config object is updated.
• The app_globals (g) object is updated (this only happens for options explicitly defined in the app_globals module).

The following lists a key parameter, but this should be replaced by whichever config options want to be updated, eg:

```python
get_action('config_option_update')({}, {
    'ckan.site_title': 'My Open Data site',
    'ckan.homepage_layout': 2,
})
```

**Parameters** key *(string)* – a configuration option key (eg ckan.site_title). It must be present on the update_configuration_schema

**Returns** a dictionary with the options set

**Return type** dictionary

**Note:** You can see all available runtime-editable configuration options calling the `config_option_list()` action

**Note:** Extensions can modify which configuration options are runtime-editable. For details, check *Making configuration options runtime-editable.*

**Warning:** You should only add config options that you are comfortable they can be edited during runtime, such as ones you’ve added in your own extension, or have reviewed the use of in core CKAN.

### 4.9.4 ckan.logic.action.patch

New in version 2.3. API functions for partial updates of existing data in CKAN

```python
ckan.logic.action.patch.package_patch(context, data_dict)
Patch a dataset (package).
```

**Parameters** id *(string)* – the id or name of the dataset

The difference between the update and patch methods is that the patch will perform an update of the provided parameters, while leaving all other parameters unchanged, whereas the update methods deletes all parameters not explicitly provided in the data_dict

You must be authorized to edit the dataset and the groups that it belongs to.

```python
ckan.logic.action.patch.resource_patch(context, data_dict)
Patch a resource.
```

**Parameters** id *(string)* – the id of the resource

The difference between the update and patch methods is that the patch will perform an update of the provided parameters, while leaving all other parameters unchanged, whereas the update methods deletes all parameters not explicitly provided in the data_dict
ckan.logic.action.patch.

**group_patch**(context, data_dict)

Patch a group

**Parameters id**(string) – the id or name of the group

The difference between the update and patch methods is that the patch will perform an update of the provided parameters, while leaving all other parameters unchanged, whereas the update methods deletes all parameters not explicitly provided in the data_dict

ckan.logic.action.patch.

**organization_patch**(context, data_dict)

Patch an organization

**Parameters id**(string) – the id or name of the organization

The difference between the update and patch methods is that the patch will perform an update of the provided parameters, while leaving all other parameters unchanged, whereas the update methods deletes all parameters not explicitly provided in the data_dict

**4.9.5 ckan.logic.action.delete**

API functions for deleting data from CKAN.

ckan.logic.action.delete.

**user_delete**(context, data_dict)

Delete a user.

Only sysadmins can delete users.

**Parameters id**(string) – the id or username of the user to delete

ckan.logic.action.delete.

**package_delete**(context, data_dict)

Delete a dataset (package).

This makes the dataset disappear from all web & API views, apart from the trash.

You must be authorized to delete the dataset.

**Parameters id**(string) – the id or name of the dataset to delete

ckan.logic.action.delete.

**dataset_purge**(context, data_dict)

Purge a dataset.

**Warning:** Purging a dataset cannot be undone!

Purging a database completely removes the dataset from the CKAN database, whereas deleting a dataset simply marks the dataset as deleted (it will no longer show up in the front-end, but is still in the db).

You must be authorized to purge the dataset.

**Parameters id**(string) – the name or id of the dataset to be purged

ckan.logic.action.delete.

**resource_delete**(context, data_dict)

Delete a resource from a dataset.

You must be a sysadmin or the owner of the resource to delete it.

**Parameters id**(string) – the id of the resource

ckan.logic.action.delete.

**resource_view_delete**(context, data_dict)

Delete a resource_view.

**Parameters id**(string) – the id of the resource_view
ckan.logic.action.delete.resource_view_clear(context, data_dict)
Delete all resource views, or all of a particular type.

Parameters view_types (list) – specific types to delete (optional)

ckan.logic.action.delete.package_relationship_delete(context, data_dict)
Delete a dataset (package) relationship.
You must be authorised to delete dataset relationships, and to edit both the subject and the object datasets.

Parameters

• subject (string) – the id or name of the dataset that is the subject of the relationship
• object (string) – the id or name of the dataset that is the object of the relationship
• type (string) – the type of the relationship

ckan.logic.action.delete.member_delete(context, data_dict=None)
Remove an object (e.g. a user, dataset or group) from a group.
You must be authorized to edit a group to remove objects from it.

Parameters

• id (string) – the id of the group
• object (string) – the id or name of the object to be removed
• object_type (string) – the type of the object to be removed, e.g. package or user

ckan.logic.action.delete.group_delete(context, data_dict)
Delete a group.
You must be authorized to delete the group.

Parameters id (string) – the name or id of the group

ckan.logic.action.delete.organization_delete(context, data_dict)
Delete an organization.
You must be authorized to delete the organization and no datasets should belong to the organization unless ‘ckan.auth.create_unowned_dataset=True’

Parameters id (string) – the name or id of the organization

ckan.logic.action.delete.group_purge(context, data_dict)
Purge a group.

Warning: Purging a group cannot be undone!

Purging a group completely removes the group from the CKAN database, whereas deleting a group simply marks the group as deleted (it will no longer show up in the frontend, but is still in the db).
Datasets in the organization will remain, just not in the purged group.
You must be authorized to purge the group.

Parameters id (string) – the name or id of the group to be purged

ckan.logic.action.delete.organization_purge(context, data_dict)
Purge an organization.

4.9. Action API reference 187
Warning: Purging an organization cannot be undone!

Purging an organization completely removes the organization from the CKAN database, whereas deleting an organization simply marks the organization as deleted (it will no longer show up in the frontend, but is still in the db).

Datasets owned by the organization will remain, just not in an organization any more.

You must be authorized to purge the organization.

Parameters

id (string) – the name or id of the organization to be purged

ckan.logic.action.delete.task_status_delete(context, data_dict)
Delete a task status.

You must be a sysadmin to delete task statuses.

Parameters

id (string) – the id of the task status to delete

ckan.logic.action.delete.vocabulary_delete(context, data_dict)
Delete a tag vocabulary.

You must be a sysadmin to delete vocabularies.

Parameters

id (string) – the id of the vocabulary

ckan.logic.action.delete.tag_delete(context, data_dict)
Delete a tag.

You must be a sysadmin to delete tags.

Parameters

• id (string) – the id or name of the tag
• vocabulary_id (string) – the id or name of the vocabulary that the tag belongs to
  (optional, default: None)

ckan.logic.action.delete.unfollow_user(context, data_dict)
Stop following a user.

Parameters

id (string) – the id or name of the user to stop following

ckan.logic.action.delete.unfollow_dataset(context, data_dict)
Stop following a dataset.

Parameters

id (string) – the id or name of the dataset to stop following

ckan.logic.action.delete.group_member_delete(context, data_dict=None)
Remove a user from a group.

You must be authorized to edit the group.

Parameters

• id (string) – the id or name of the group
• username (string) – name or id of the user to be removed

ckan.logic.action.delete.organization_member_delete(context, data_dict=None)
Remove a user from an organization.

You must be authorized to edit the organization.

Parameters
• **id** (*string*) – the id or name of the organization

• **username** (*string*) – name or id of the user to be removed

```python
ckan.logic.action.delete.unfollow_group(context, data_dict)
```
Stop following a group.

**Parameters**

- **id** (*string*) – the id or name of the group to stop following

```python
ckan.logic.action.delete.job_clear(context, data_dict)
```
Clear background job queues.

**Parameters**

- **queues** (*list*) – The queues to clear. If not given then ALL queues are cleared.

**Returns**

- The cleared queues.

**Return type**

- list

New in version 2.7.

```python
ckan.logic.action.delete.job_cancel(context, data_dict)
```
Cancel a queued background job.

**Parameters**

- **id** (*string*) – The ID of the background job.

New in version 2.7.
The following sections will teach you how to customize and extend CKAN’s features by developing your own CKAN extensions.

See also:
Some core extensions come packaged with CKAN. Core extensions don’t need to be installed before you can use them as they’re installed when you install CKAN, they can simply be enabled by following the setup instructions in each extension’s documentation (some core extensions are already enabled by default). For example, the datastore extension, multilingual extension, and stats extension are all core extensions, and the data viewer also uses core extensions to enable data previews for different file formats.

See also:
External extensions are CKAN extensions that don’t come packaged with CKAN, but must be downloaded and installed separately. Find external extensions at https://extensions.ckan.org/. Again, follow each extension’s own documentation to install, setup, and use the extension.

5.1 Writing extensions tutorial

This tutorial will walk you through the process of creating a simple CKAN extension, and introduce the core concepts that CKAN extension developers need to know along the way. As an example, we’ll use the example_iauthfunctions extension that’s packaged with CKAN. This is a simple CKAN extension that customizes some of CKAN’s authorization rules.

5.1.1 Installing CKAN

Before you can start developing a CKAN extension, you’ll need a working source install of CKAN on your system. If you don’t have a CKAN source install already, follow the instructions in Installing CKAN from source before continuing.
5.1.2 Creating a new extension

**Extensions**

A CKAN extension is a Python package that modifies or extends CKAN. Each extension contains one or more plugins that must be added to your CKAN config file to activate the extension’s features.

You can use the `paster create` command to create an “empty” extension from a template. First, activate your CKAN virtual environment:

```
. /usr/lib/ckan/default/bin/activate
```

When you run the `paster create` command, your new extension’s directory will be created in the current working directory by default (you can override this with the `-o` option), so change to the directory that you want your extension to be created in. Usually you’ll want to track your extension code using a version control system such as `git`, so you wouldn’t want to create your extension in the `ckan` source directory because that directory already contains the CKAN `git` repo. Let’s use the parent directory instead:

```
cd /usr/lib/ckan/default/src
```

Now run the `paster create` command to create your extension:

```
paster --plugin=ckan create -t ckanext ckanext-iauthfunctions
```

**Note:** The last argument to the `paster create` command (`ckanext-iauthfunctions` in this example) is the name for your next extension. CKAN extension names *have* to begin with `ckanext-`.

The command will ask you to answer a few questions. The answers you give will end up in your extension’s `setup.py` file (where you can edit them later if you want).

Once this command has completed, your new CKAN extension’s project directory will have been created and will contain a few directories and files to get you started:

```
ckanext-iauthfunctions/
   ckanext/
      __init__.py
     iauthfunctions/
      __init__.py
     ckanext_iauthfunctions.egg-info/
     setup.py
```

`ckanext_iauthfunctions.egg_info` is a directory containing automatically generated metadata about your project. It’s used by Python’s packaging and distribution tools. In general, you don’t need to edit or look at anything in this directory, and you should not add it to version control.

`setup.py` is the setup script for your project. As you’ll see later, you use this script to install your project into a virtual environment. It contains several settings that you’ll update as you develop your project.

`ckanext/iauthfunctions` is the Python package directory where we’ll add the source code files for our extension.

5.1.3 Creating a plugin class
Plugins

Each CKAN extension contains one or more plugins that provide the extension’s features.

Now create the file `ckanext-iauthfunctions/ckanext/iauthfunctions/plugin.py` with the following contents:

```python
# encoding: utf-8
import ckan.plugins as plugins

class ExampleIAuthFunctionsPlugin(plugins.SingletonPlugin):
    pass
```

Our plugin is a normal Python class, named `ExampleIAuthFunctionsPlugin` in this example, that inherits from CKAN’s `SingletonPlugin` class.

**Note:** Every CKAN plugin class should inherit from `SingletonPlugin`.

5.1.4 Adding the plugin to `setup.py`

Now let’s add our class to the `entry_points` in `setup.py`. This identifies the plugin class to CKAN once the extension is installed in CKAN’s virtualenv, and associates a plugin name with the class. Edit `ckanext-iauthfunctions/setup.py` and add a line to the `entry_points` section like this:

```python
entry_points='''
    [ckan.plugins]
    example_iauthfunctions=ckanext.iauthfunctions.plugin:ExampleIAuthFunctionsPlugin
''
```

5.1.5 Installing the extension

When you *install CKAN*, you create a Python virtual environment in a directory on your system (e.g., `/usr/lib/ckan/default` by default) and install the CKAN Python package and the other packages that CKAN depends on into this virtual environment. Before we can use our plugin, we must install our extension into our CKAN virtual environment.

Make sure your virtualenv is activated, change to the extension’s directory, and run `python setup.py develop`:

```
. /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src/ckanext-iauthfunctions
python setup.py develop
```

5.1.6 Enabling the plugin

An extension’s plugins must be added to the `ckan.plugins` setting in your CKAN config file so that CKAN will call the plugins’ methods. The name that you gave to your plugin class in the *left-hand-side of the assignment in the setup.py file* (`example_iauthfunctions` in this example) is the name you’ll use for your plugin in CKAN’s config file:

```python
ckan.plugins = stats text_view recline_view example_iauthfunctions
```
CKAN documentation, Release 2.8.5

You should now be able to start CKAN in the development web server and have it start up without any problems:

```
$ paster serve /etc/ckan/default/development.ini
Starting server in PID 13961.
serving on 0.0.0.0:5000 view at http://127.0.0.1:5000
```

If your plugin is in the `ckan.plugins` setting and CKAN starts without crashing, then your plugin is installed and CKAN can find it. Of course, your plugin doesn’t do anything yet.

5.1.7 Troubleshooting

**PluginNotFoundException**

If CKAN crashes with a `PluginNotFoundException` like this:

```
ckan.plugins.core.PluginNotFoundException: example_iauthfunctions
```

then:

- Check that the name you’ve used for your plugin in your CKAN config file is the same as the name you’ve used in your extension’s `setup.py` file
- Check that you’ve run `python setup.py develop` in your extension’s directory, with your CKAN virtual environment activated. Every time you add a new plugin to your extension’s `setup.py` file, you need to run `python setup.py develop` again before you can use the new plugin.

**ImportError**

If you get an `ImportError` from CKAN relating to your plugin, it’s probably because the path to your plugin class in your `setup.py` file is wrong.

5.1.8 Implementing the IAuthFunctions plugin interface

**Plugin interfaces**

CKAN provides a number of plugin interfaces that plugins must implement to hook into CKAN and modify or extend it. Each plugin interface defines a number of methods that a plugin that implements the interface must provide. CKAN will call your plugin’s implementations of these methods, to allow your plugin to do its stuff.

To modify CKAN’s authorization behavior, we’ll implement the `IAuthFunctions` plugin interface. This interface defines just one method, that takes no parameters and returns a dictionary:

```
get_auth_functions()  # Return the authorization functions provided by this plugin.
```

**Action functions and authorization functions**

At this point, it’s necessary to take a short diversion to explain how authorization works in CKAN.

Every action that can be carried out using the CKAN web interface or API is implemented by an *action function* in one of the four files `ckan/logic/action/{create, delete, get, update}.py`. 
For example, when creating a dataset either using the web interface or using the `package_create()` API call, `ckan.logic.action.create.package_create()` is called. There’s also `ckan.logic.action.get.package_show()`, `ckan.logic.action.update.package_update()`, and `ckan.logic.action.delete.package_delete()`.

For a full list of the action functions available in CKAN, see the Action API reference.

Each action function has a corresponding authorization function in one of the four files `ckan/logic/auth/{create,delete,get,update}.py`, CKAN calls this authorization function to decide whether the user is authorized to carry out the requested action. For example, when creating a new package using the web interface or API, `ckan.logic.auth.create.package_create()` is called.

The `IAuthFunctions` plugin interface allows CKAN plugins to hook into this authorization system to add their own authorization functions or override the default authorization functions. In this way, plugins have complete control to customize CKAN’s auth.

Whenever a user tries to create a new group via the web interface or the API, CKAN calls the `group_create()` authorization function to decide whether to allow the action. Let’s override this function and simply prevent anyone from creating new groups (Note: this is default behavior. In order to go further, you need to change `ckan.auth.user_create_groups` to `True` in configuration file). Edit your `plugin.py` file so that it looks like this:

```python
# encoding: utf-8
import ckan.plugins as plugins

def group_create(context, data_dict=None):
    return {'success': False, 'msg': 'No one is allowed to create groups'}

class ExampleIAuthFunctionsPlugin(plugins.SingletonPlugin):
    plugins.implements(plugins.IAuthFunctions)
    def get_auth_functions(self):
        return {'group_create': group_create}
```

Our `ExampleIAuthFunctionsPlugin` class now calls `implements()` to tell CKAN that it implements the `IAuthFunctions` interface, and provides an implementation of the interface’s `get_auth_functions()` method that overrides the default `group_create()` function with a custom one. This custom function simply returns `{'success': False}` to refuse to let anyone create a new group.

If you now restart CKAN and reload the `/group` page, as long as you’re not a sysadmin user you should see the Add Group button disappear. The CKAN web interface automatically hides buttons that the user is not authorized to use. Visiting `/group/new` directly will redirect you to the login page. If you try to call `group_create()` via the API, you’ll receive an Authorization Error from CKAN:

```
$ http 127.0.0.1:5000/api/3/action/group_create Authorization:*** name=my_group
HTTP/1.0 403 Forbidden
Access-Control-Allow-Headers: X-CKAN-API-KEY, Authorization, Content-Type
Access-Control-Allow-Methods: POST, PUT, GET, DELETE, OPTIONS
Access-Control-Allow-Origin: *
Cache-Control: no-cache
Content-Length: 2866
Content-Type: application/json; charset=utf-8
Date: Wed, 12 Jun 2013 13:38:01 GMT
Pragma: no-cache
Server: PasteWSGIServer/0.5 Python/2.7.4
```

(continues on next page)
If you’re logged in as a sysadmin user however, you’ll still be able to create new groups. Sysadmin users can always carry out any action, they bypass the authorization functions.

### 5.1.9 Using the plugins toolkit

Let’s make our custom authorization function a little smarter, and allow only users who are members of a particular group named `curators` to create new groups.

First run CKAN, login and then create a new group called `curators`. Then edit `plugin.py` so that it looks like this:

**Note:** This version of `plugin.py` will crash if the user is not logged in or if the site doesn’t have a group called `curators`. You’ll want to create a `curators` group in your CKAN before editing your plugin to look like this. See *Exception handling* below.

```python
# encoding: utf-8

import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit

def group_create(context, data_dict=None):
    # Get the user name of the logged-in user.
    user_name = context['user']

    # Get a list of the members of the 'curators' group.
    members = toolkit.get_action('member_list')({
        'data_dict': {'id': 'curators', 'object_type': 'user'}})

    # 'members' is a list of (user_id, object_type, capacity) tuples, we're
    # only interested in the user_ids.
    member_ids = [member_tuple[0] for member_tuple in members]

    # We have the logged-in user's user name, get their user id.
    convert_user_name_or_id_to_id = toolkit.get_converter(
        'convert_user_name_or_id_to_id')
    user_id = convert_user_name_or_id_to_id(user_name, context)

    # Finally, we can test whether the user is a member of the curators group.
    if user_id in member_ids:
        return {'success': True}
    else:
        return {'error': {"__type": "Authorization Error",
                          "message": "Access denied"}},
        "help": "Create a new group...",
        "success": false
```

(continues on next page)
class ExampleIAuthFunctionsPlugin(plugins.SingletonPlugin):
    plugins.implements(plugins.IAuthFunctions)
    def get_auth_functions(self):
        return {'group_create': group_create}

context

The context parameter of our group_create() function is a dictionary that CKAN passes to all authorization and action functions containing some computed variables. Our function gets the name of the logged-in user from context:

    user_name = context['user']

data_dict

The data_dict parameter of our group_create() function is another dictionary that CKAN passes to all authorization and action functions. data_dict contains any data posted by the user to CKAN, eg. any fields they’ve completed in a web form they’re submitting or any JSON fields they’ve posted to the API. If we inspect the contents of the data_dict passed to our group_create() authorization function, we’ll see that it contains the details of the group the user wants to create:

    {'description': u'A really cool group',
     'image_url': u'',
     'name': u'my_group',
     'title': u'My Group',
     'type': 'group',
     'users': [{'capacity': 'admin', 'name': u'seanh'}]}

The plugins toolkit

CKAN’s plugins toolkit is a Python module containing core CKAN functions, classes and exceptions for use by CKAN extensions.

The toolkit’s get_action() function returns a CKAN action function. The action functions available to extensions are the same functions that CKAN uses internally to carry out actions when users make requests to the web interface or API. Our code uses get_action() to get the member_list() action function, which it uses to get a list of the members of the curators group:

    members = toolkit.get_action('member_list')({
        data_dict={'id': 'curators', 'object_type': 'user'})

Calling member_list() in this way is equivalent to posting the same data dict to the /api/3/action/member_list API endpoint. For other action functions available from get_action(), see Action API reference.
The toolkit’s `get_validator()` function returns validator and converter functions from `ckan.logic.converters` for plugins to use. This is the same set of converter functions that CKAN’s action functions use to convert user-provided data. Our code uses `get_validator()` to get the `convert_user_name_or_id_to_id()` converter function, which it uses to convert the name of the logged-in user to their user id:

```python
convert_user_name_or_id_to_id = toolkit.get_converter('convert_user_name_or_id_to_id')
user_id = convert_user_name_or_id_to_id(user_name, context)
```

Finally, we can test whether the logged-in user is a member of the `curators` group, and allow or refuse the action:

```python
if user_id in member_ids:
    return {'success': True}
else:
    return {'success': False,
            'msg': 'Only curators are allowed to create groups'}
```

### 5.1.10 Exception handling

There are two bugs in our `plugin.py` file that need to be fixed using exception handling. First, the class will crash if the site does not have a group named `curators`.

**Tip:** If you’ve already created a `curators` group and want to test what happens when the site has no `curators` group, you can use CKAN’s command line interface to :ref:`clean and reinitialize your database <database management>`.

Try visiting the `/group` page in CKAN with our `example_iauthfunctions` plugin activated in your CKAN config file and with no `curators` group in your site. If you have `debug = false` in your CKAN config file, you’ll see something like this in your browser:

```
Error 500
Server Error
An internal server error occurred
```

If you have `debug = true` in your CKAN config file, then you’ll see a traceback page with details about the crash. You’ll also get a 500 Server Error if you try to create a group using the `group_create` API action.

To handle the situation where the site has no `curators` group without crashing, we’ll have to handle the exception that CKAN’s `member_list()` function raises when it’s asked to list the members of a group that doesn’t exist. Replace the `member_list` line in your `plugin.py` file with these lines:

```python
try:
    members = toolkit.get_action('member_list')(
        data_dict={'id': 'curators', 'object_type': 'user'})
except toolkit.ObjectNotFound:
    # The curators group doesn't exist.
    return {'success': False,
            'msg': "The curators groups doesn't exist, so only sysadmins"}
```

(continues on next page)
With these `try` and `except` clauses added, we should be able to load the `/group` page and add groups, even if there isn’t already a group called `curators`.

Second, `plugin.py` will crash if a user who is not logged-in tries to create a group. If you logout of CKAN, and then visit `/group/new` you’ll see another 500 Server Error. You’ll also get this error if you post to the `group_create()` API action without providing an API key.

When the user isn’t logged in, `context['user']` contains the user’s IP address instead of a user name:

```python
{'model': <module 'ckan.model' from ...>, 'user': u'127.0.0.1'}
```

When we pass this IP address as the user name to `convert_user_name_or_id_to_id()`, the converter function will raise an exception because no user with that user name exists. We need to handle that exception as well, replace the `convert_user_name_or_id_to_id` line in your `plugin.py` file with these lines:

```python
convert_user_name_or_id_to_id = toolkit.get_converter('convert_user_name_or_id_to_id')
try:
    user_id = convert_user_name_or_id_to_id(user_name, context)
except toolkit.Invalid:
    # The user doesn't exist (e.g. they're not logged-in).
    return {'success': False, 'msg': 'You must be logged-in as a member of the curators group to create new groups.'}
```

### 5.1.11 We’re done!

Here’s our final, working `plugin.py` module in full:

```python
# encoding: utf-8
import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit

def group_create(context, data_dict=None):
    # Get the user name of the logged-in user.
    user_name = context['user']

    # Get a list of the members of the 'curators' group.
    try:
        members = toolkit.get_action('member_list')(data_dict={'id': 'curators', 'object_type': 'user'})
    except toolkit.ObjectNotFound:
        # The curators group doesn't exist.
        return {'success': False, 'msg': 'The curators groups doesn't exist, so only sysadmins are authorized to create groups.'}

    # 'members' is a list of (user_id, object_type, capacity) tuples, we're
```

(continues on next page)
In working through this tutorial, you’ve covered all the key concepts needed for writing CKAN extensions, including:

- Creating an extension
- Creating a plugin within your extension
- Adding your plugin to your extension’s setup.py file, and installing your extension
- Making your plugin implement one of CKAN’s plugin interfaces
- Using the plugins toolkit
- Handling exceptions

### 5.1.12 Troubleshooting

#### AttributeError

If you get an AttributeError like this one:

```python
AttributeError: 'ExampleIAuthFunctionsPlugin' object has no attribute 'get_auth_functions'
```

it means that your plugin class does not implement one of the plugin interface’s methods. A plugin must implement every method of every plugin interface that it implements.

**Todo:** Can you use inherit=True to avoid having to implement them all?
Other AttributeErrors can happen if your method returns the wrong type of value, check the documentation for each plugin interface method to see what your method should return.

**TypeError**

If you get a TypeError like this one:

```
TypeError: get_auth_functions() takes exactly 3 arguments (1 given)
```

it means that one of your plugin methods has the wrong number of parameters. A plugin has to implement each method in a plugin interface with the same parameters as in the interface.

### 5.2 Using custom config settings in extensions

Extensions can define their own custom config settings that users can add to their CKAN config files to configure the behavior of the extension.

Continuing with the `IAuthFunctions` example from *Writing extensions tutorial*, let’s make an alternative version of the extension that allows users to create new groups if a new config setting `ckan.iauthfunctions.users_can_create_groups` is True:

```
# encoding: utf-8

from ckan.common import config

import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit

def group_create(context, data_dict=None):
    # Get the value of the ckan.iauthfunctions.users_can_create_groups
    # setting from the CKAN config file as a string, or False if the setting
    # isn't in the config file.
    users_can_create_groups = config.get('ckan.iauthfunctions.users_can_create_groups', False)

    # Convert the value from a string to a boolean.
    users_can_create_groups = toolkit.asbool(users_can_create_groups)

    if users_can_create_groups:
        return {'success': True}
    else:
        return {'success': False,
                'msg': 'Only sysadmins can create groups'}

class ExampleIAuthFunctionsPlugin(plugins.SingletonPlugin):
    plugins.implements(plugins.IAuthFunctions)
    def get_auth_functions(self):
        return {'group_create': group_create}
```

The `group_create` authorization function in this plugin uses `config` to read the setting from the config file, then calls `ckan.plugins.toolkit.asbool()` to convert the value from a string (all config settings values are
strings, when read from the file) to a boolean.

**Note:** There are also `asint()` and `aslist()` functions in the plugins toolkit.

With this plugin enabled, you should find that users can create new groups if you have `ckan.iauthfunctions.users_can_create_groups = True` in the `[app:main]` section of your CKAN config file. Otherwise, only sysadmin users will be allowed to create groups.

**Note:** Names of config settings provided by extensions should include the name of the extension, to avoid conflicting with core config settings or with config settings from other extensions. See *Avoid name clashes*.

**Note:** The users still need to be logged-in to create groups. In general creating, updating or deleting content in CKAN requires the user to be logged-in to a registered user account, no matter what the relevant authorization function says.

### 5.3 Making configuration options runtime-editable

Extensions can allow certain configuration options to be edited during runtime, as opposed to having to edit the configuration file and restart the server.

**Warning:** Only configuration options which are not critical, sensitive or could cause the CKAN instance to break should be made runtime-editable. You should only add config options that you are comfortable they can be edited during runtime, such as ones you’ve added in your own extension, or have reviewed the use of in core CKAN.

**Note:** Only sysadmin users are allowed to modify runtime-editable configuration options.

In this tutorial we will show how to make changes to our extension to make two configuration options runtime-editable: `ckan.datasets_per_page` and a custom one named `ckanext.example_iconfigurer.test_conf`. You can see the changes in the `example_iconfigurer` extension that’s packaged with CKAN. If you haven’t done yet, you should check the *Writing extensions tutorial* first.

This tutorial assumes that we have CKAN running on the paster development server at `http://localhost:5000`, and that we are using the API key of a sysadmin user.

First of all, let’s call the `config_option_list()` API action to see what configuration options are editable during runtime (the | python -m json.tool bit at the end is added to format the output nicely):

```
```

(continues on next page)
We can see that the two options that we want to make runtime-editable are not on the list. Trying to update one of them with the `config_option_update()` action would return an error.

To include them, we need to add them to the schema that CKAN will use to decide which configuration options can be edited safely at runtime. This is done with the `update_config_schema()` method of the `IConfigurer` interface.

Let’s have a look at how our extension should look like:

```python
# encoding: utf-8

from six import text_type

import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit

class ExampleIConfigurerPlugin(plugins.SingletonPlugin):
    plugins.implements(plugins.IConfigurer)
    # IConfigurer
    def update_config_schema(self, schema):
        ignore_missing = toolkit.get_validator('ignore_missing')
        is_positive_integer = toolkit.get_validator('is_positive_integer')

        schema.update({
            # This is an existing CKAN core configuration option, we are just
            # making it available to be editable at runtime
            'ckan.datasets_per_page': [ignore_missing, is_positive_integer],

            # This is a custom configuration option
            'ckanext.example_iConfigurer.test_conf': [ignore_missing, text_type],
        })

        return schema
```

The `update_config_schema` method will receive the default schema for runtime-editable configuration options used by CKAN core. We can then add keys to it to make new options runtime-editable (or remove them if we don’t want them to be runtime-editable). The schema is a dictionary mapping configuration option keys to lists of validator and converter functions to be applied to those keys. To get validator functions defined in CKAN core we use the `get_validator()` function.

**Note:** Make sure that the first validator applied to each key is the `ignore_missing` one, otherwise this key will
need to be always set when updating the configuration.

Restart the web server and do another request to the `config_option_list()` API action:

```bash
{
    "help": "http://localhost:5000/api/3/action/help_show?name=config_option_list",
    "result": [
        "ckan.datasets_per_page",
        "ckanext.example_iconfigurer.test_conf",
        "ckan.site_custom_css",
        "ckan.main_css",
        "ckan.site_title",
        "ckan.site_about",
        "ckan.site_url",
        "ckan.site_logo",
        "ckan.site_description",
        "ckan.site_intro_text",
        "ckan.homepage_style",
        "ckan.hola"
    ],
    "success": true
}
```

Our two new configuration options are available to be edited at runtime. We can test it calling the `config_option_update()` action:

```bash
{
    "result": {
        "ckan.datasets_per_page": 5
    },
    "success": true
}
```

The configuration has now been updated. If you visit the main search page at `http://localhost:5000/dataset` only 5 datasets should appear in the results as opposed to the usual 20.

At this point both our configuration options can be updated via the API, but we also want to make them available on the administration interface so non-technical users don’t need to use the API to change them.

To do so, we will extend the CKAN core template as described in the `Customizing CKAN’s templates` documentation. First add the `update_config()` method to your plugin and register the extension `templates` folder:

```python
# encoding: utf-8

from six import text_type
import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit

class ExampleIConfigurerPlugin(plugins.SingletonPlugin):
    plugins.implements(plugins.IConfigurer)
    (continues on next page)
```
# IConfigurer

def update_config(self, config):
    # Add extension templates directory
    toolkit.add_template_directory(config, 'templates')

def update_config_schema(self, schema):
    ignore_missing = toolkit.get_validator('ignore_missing')
    is_positive_integer = toolkit.get_validator('is_positive_integer')

    schema.update({
        # This is an existing CKAN core configuration option, we are just
        # making it available to be editable at runtime
        'ckan.datasets_per_page': [ignore_missing, is_positive_integer],

        # This is a custom configuration option
        'ckanext.example_iconfigurer.test_conf': [ignore_missing, text_type],
    })

    return schema

Now create a new file config.html file under ckanext/yourextension/templates/admin/ with the following contents:

{% ckan_extends %}
{% import 'macros/form.html' as form %}
{% block admin_form %}
    {{ super() }}
    <h3>Custom configuration options </h3>
    {{ form.input('ckan.datasets_per_page', id='field-ckan.datasets_per_page', label=_(
        'Datasets per page'), value=data['ckan.datasets_per_page'], error=errors['ckan.
        datasets_per_page']) }}

    {{ form.input('ckanext.example_iconfigurer.test_conf', id='field-ckanext.example_
        iconfigurer.test_conf', label=_("Test conf"), value=data['ckanext.example_
            iconfigurer.test_conf'], error=errors['ckanext.example_iconfigurer.test_conf']) }}

{% endblock %}
{% block admin_form_help %}
    {{ super() }}
    <p><strong>Datasets per page</strong>: Number of datasets displayed in dataset
       listings (eg search page). </p>

(continues on next page)
This template is extending the default core one. The first block adds two new fields for our configuration options below the existing ones. The second adds a helper text for them on the left hand column.

Restart the server and navigate to http://localhost:5000/ckan-admin/config. You should see the newfields at the bottom of the form:

Updating the values on the form should update the configuration as before.

### 5.4 Testing extensions

CKAN extensions can have their own tests that are run using nosetests in much the same way as running CKAN’s own tests (see Testing CKAN).

Continuing with our example_iauthfunctions extension, first we need a CKAN config file to be used when running our tests. Create the file ckanext-iauthfunctions/test.ini with the following contents:

```ini
[app:main]
use = config:../ckan/test-core.ini
```

The use line declares that this config file inherits the settings from the config file used to run CKAN’s own tests (../ckan should be the path to your CKAN source directory, relative to your test.ini file).

The test.ini file is a CKAN config file just like your /etc/ckan/default/development.ini and /etc/ckan/default/production.ini files, and it can contain any CKAN config file settings that you want CKAN to use when running your tests, for example:
[app:main]
use = config:../ckan/test-core.ini
ckan.site_title = My Test CKAN Site
ckan.site_description = A test site for testing my CKAN extension

Next, make the directory that will contain our test modules:

```bash
mkdir ckanext-iauthfunctions/ckanext/iauthfunctions/tests/
```

Finally, create the file `ckanext-iauthfunctions/ckanext/iauthfunctions/tests/test_iauthfunctions.py` with the following contents:

```python
# encoding: utf-8

'''Tests for the ckanext.example_iauthfunctions extension.
'''

from nose.tools import assert_raises
from nose.tools import assert_equal

import ckan.model as model
import ckan.plugins
from ckan.plugins.toolkit import NotAuthorized, ObjectNotFound

    context = {
        'ignore_auth': False,
        'user': curator['name']
    }
    helpers.call_action('group_create', context, name=name)
```

(continues on next page)
To run these extension tests, cd into the ckanext-iauthfunctions directory and run this command:

```
nosetests --ckan --with- pylons=test.ini ckanext/iauthfunctions/tests
```

Some notes on how these tests work:

- Nose has lots of useful functions for testing, see the nose documentation.
- We’re using a paste.fixture.TestApp object to simulate sending HTTP requests to the CKAN API or frontend. See Testing Applications with Paste for some documentation of this.
- We’re calling ckan.tests.call_action_api() to post (simulated) HTTP requests to the CKAN API. This is a convenience function that CKAN provides for its own tests.
- You might also find it useful to read the Pylons testing documentation.
- The Pylons book also has a chapter on testing.
- Avoid importing the plugin modules directly into your test modules (e.g from example_iauthfunctions import plugin_v5_custom_config_setting). This causes the plugin to be registered and loaded before the entire test run, so the plugin will be loaded for all tests. This can cause conflicts and test failures.

Todo: Link to CKAN guidelines for how to write tests, once those guidelines have been written. Also add any more extension-specific testing details here.

## 5.5 Best practices for writing extensions

### 5.5.1 Follow CKAN’s coding standards

See Contributing guide.

### 5.5.2 Use the plugins toolkit instead of importing CKAN

Try to limit your extension to interacting with CKAN only through CKAN’s plugin interfaces and plugins toolkit. It’s a good idea to keep your extension code separate from CKAN as much as possible, so that internal changes in CKAN from one release to the next don’t break your extension.

### 5.5.3 Don’t edit CKAN’s database tables

An extension can create its own tables in the CKAN database, but it should not write to core CKAN tables directly, add columns to core tables, or use foreign keys against core tables.
5.5.4 Implement each plugin class in a separate Python module

This keeps CKAN’s plugin loading order simple, see `ckan.plugins`.

5.5.5 Avoid name clashes

Many of the names you pick for your identifiers and files must be unique in relation to the names used by core CKAN and other extensions. To avoid conflicts you should prefix any public name that your extension introduces with the name of your extension. For example:

- The names of configuration settings introduced by your extension should have the form `my_extension.my_config_setting`.
- The names of templates and template snippets introduced by your extension should begin with the name of your extension:

```python
snippets/my_extension_useful_snippet.html
```

If you have added a lot of templates you can also put them into a separate folder named after your extension instead.

- The names of template helper functions introduced by your extension should begin with the name of your extension. For example:

```python
def get_helpers(self):
    '''Register the most_popular_groups() function above as a template helper function.
    '''
    # Template helper function names should begin with the name of the
    # extension they belong to, to avoid clashing with functions from
    # other extensions.
    return {'example_theme_most_popular_groups': most_popular_groups}
```

- The names of JavaScript modules introduced by your extension should begin with the name of your extension. For example `fanstatic/example_theme_popover.js`:

```javascript
// Enable JavaScript's strict mode. Strict mode catches some common
// programming errors and throws exceptions, prevents some unsafe actions from
// being taken, and disables some confusing and bad JavaScript features.
"use strict";

ckan.module('example_theme_popover', function ($) {
    return {
        initialize: function () {
            console.log("I've been initialized for element: ", this.el);
        }
    };
});
```

- The names of API action functions introduced by your extension should begin with the name of your extension. For example `my_extension_foobarize_everything`.

- The names of background job queues introduced by your extension should begin with the name of your extension. For example `my_extension:super-special-job-queue`.

5.5. Best practices for writing extensions 213
In some situations, a resource may even be shared between multiple CKAN instances, which requires an even higher degree of uniqueness for the corresponding names. In that case, you should also prefix your identifiers with the CKAN site ID, which is available via

```python
try:
    # CKAN 2.7 and later
    from ckan.common import config
except ImportError:
    # CKAN 2.6 and earlier
    from pylons import config

site_id = config[u'ckan.site_id']
```

Currently this only affects the Redis database:

- All keys in the Redis database created by your extension should be prefixed with both the CKAN site ID and your extension’s name.

### 5.5.6 Internationalize user-visible strings

All user-visible strings should be internationalized, see *String internationalization*.

### 5.5.7 Add third party libraries to requirements.txt

If your extension requires third party libraries, rather than adding them to `setup.py`, they should be added to `requirements.txt`, which can be installed with:

```bash
pip install -r requirements.txt
```

To prevent accidental breakage of your extension through backwards-incompatible behaviour of newer versions of your dependencies, their versions should be pinned, such as:

```bash
requests==2.7.0
```

On the flip side, be mindful that this could also create version conflicts with requirements of considerably newer or older extensions.

### 5.5.8 Do not automatically modify the database structure

If your extension uses custom database tables then it needs to modify the database structure, for example to add the tables after its installation or to migrate them after an update. These modifications should not be performed automatically when the extension is loaded, since this can lead to dead-locks and other problems. Instead, create a `paster command` which can be run separately.

### 5.6 Customizing dataset and resource metadata fields using `IDatasetForm`

Storing additional metadata for a dataset beyond the default metadata in CKAN is a common use case. CKAN provides a simple way to do this by allowing you to store arbitrary key/value pairs against a dataset when creating or updating the dataset. These appear under the “Additional Information” section on the web interface and in ‘extras’ field of the JSON when accessed via the API.
Default extras can only take strings for their keys and values, no validation is applied to the inputs and you cannot make them mandatory or restrict the possible values to a defined list. By using CKAN’s IDatasetForm plugin interface, a CKAN plugin can add custom, first-class metadata fields to CKAN datasets, and can do custom validation of these fields.

See also:

In this tutorial we are assuming that you have read the Writing extensions tutorial

5.6.1 CKAN schemas and validation

When a dataset is created, updated or viewed, the parameters passed to CKAN (e.g. via the web form when creating or updating a dataset, or posted to an API end point) are validated against a schema. For each parameter, the schema will contain a corresponding list of functions that will be run against the value of the parameter. Generally these functions are used to validate the value (and raise an error if the value fails validation) or convert the value to a different value.

For example, the schemas can allow optional values by using the ignore_missing() validator or check that a dataset exists using package_id_exists(). A list of available validators can be found at the Validator functions reference. You can also define your own Custom validators.

We will be customizing these schemas to add our additional fields. The IDatasetForm interface allows us to override the schemas for creation, updating and displaying of datasets.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create_package_schema()</td>
<td>Return the schema for validating new dataset dicts.</td>
</tr>
<tr>
<td>update_package_schema()</td>
<td>Return the schema for validating updated dataset dicts.</td>
</tr>
<tr>
<td>show_package_schema()</td>
<td>Return a schema to validate datasets before they’re shown to the user.</td>
</tr>
<tr>
<td>is_fallback()</td>
<td>Return True if this plugin is the fallback plugin.</td>
</tr>
<tr>
<td>package_types()</td>
<td>Return an iterable of package types that this plugin handles.</td>
</tr>
</tbody>
</table>

CKAN allows you to have multiple IDatasetForm plugins, each handling different dataset types. So you could customize the CKAN web front end, for different types of datasets. In this tutorial we will be defining our plugin as the fallback plugin. This plugin is used if no other IDatasetForm plugin is found that handles that dataset type.

The IDatasetForm also has other additional functions that allow you to provide a custom template to be rendered for the CKAN front end, but we will not be using them for this tutorial.

Adding custom fields to datasets

Create a new plugin named ckanext-extrafields and create a class named ExampleIDatasetFormPlugins inside ckanext-extrafields/ckanext/extrafields/plugin.py that implements the IDatasetForm interface and inherits from SingletonPlugin and DefaultDatasetForm.

```python
# encoding: utf-8

import ckan.plugins as p
import ckan.plugins.toolkit as tk

class ExampleIDatasetFormPlugin(p.SingletonPlugin, tk.DefaultDatasetForm):
    p.implements(p.IDatasetForm)
```

5.6. Customizing dataset and resource metadata fields using IDatasetForm
Updating the CKAN schema

The `create_package_schema()` function is used whenever a new dataset is created, we’ll want update the default schema and insert our custom field here. We will fetch the default schema defined in `default_create_package_schema()` by running `create_package_schema()`’s super function and update it.

```python
def create_package_schema(self):
    # let's grab the default schema in our plugin
    schema = super(ExampleIDatasetFormPlugin, self).create_package_schema()
    # our custom field
    schema.update({
        'custom_text': [tk.get_validator('ignore_missing'),
                        tk.get_converter('convert_to_extras')]
    })
    return schema
```

The CKAN schema is a dictionary where the key is the name of the field and the value is a list of validators and converters. Here we have a validator to tell CKAN to not raise a validation error if the value is missing and a converter to convert the value to and save as an extra. We will want to change the `update_package_schema()` function with the same update code.

```python
def update_package_schema(self):
    schema = super(ExampleIDatasetFormPlugin, self).update_package_schema()
    # our custom field
    schema.update({
        'custom_text': [tk.get_validator('ignore_missing'),
                        tk.get_converter('convert_to_extras')]
    })
    return schema
```

The `show_package_schema()` is used when the `package_show()` action is called, we want the default_show_package_schema to be updated to include our custom field. This time, instead of converting to an extras field, we want our field to be converted from an extras field. So we want to use the `convert_from_extras()` converter.

```python
def show_package_schema(self):
    schema = super(ExampleIDatasetFormPlugin, self).show_package_schema()
    schema.update({
        'custom_text': [tk.get_converter('convert_from_extras'),
                        tk.get_validator('ignore_missing')]
    })
    return schema
```

Dataset types

The `package_types()` function defines a list of dataset types that this plugin handles. Each dataset has a field containing its type. Plugins can register to handle specific types of dataset and ignore others. Since our plugin is not for any specific type of dataset and we want our plugin to be the default handler, we update the plugin code to contain the following:

```python
def is_fallback(self):
    return schema
```

(continues on next page)
# Return True to register this plugin as the default handler for package types not handled by any other IDatasetForm plugin.
return True

def package_types(self):
    # This plugin doesn't handle any special package types, it just registers itself as the default (above).
    return []

### Updating templates

In order for our new field to be visible on the CKAN front-end, we need to update the templates. Add an additional line to make the plugin implement the IConfigurer interface

class ExampleIDatasetFormPlugin(p.SingletonPlugin, tk.DefaultDatasetForm):
    p.implements(p.IDatasetForm)
    p.implements(p.IConfigurer)

This interface allows to implement a function update_config() that allows us to update the CKAN config, in our case we want to add an additional location for CKAN to look for templates. Add the following code to your plugin.

def update_config(self, config):
    # Add this plugin's templates dir to CKAN's extra_template_paths, so that CKAN will use this plugin's custom templates.
    tk.add_template_directory(config, 'templates')

You will also need to add a directory under your extension directory to store the templates. Create a directory called `ckanext-extrafields/ckanext/extrafields/templates/` and the subdirectories `ckanext-extrafields/ckanext/extrafields/templates/package/snippets/`.

We need to override a few templates in order to get our custom field rendered. A common option when using a custom schema is to remove the default custom field handling that allows arbitrary key/value pairs. Create a template file in our templates directory called `package/snippets/package_metadata_fields.html` containing

```html
{% ckan_extends %}

{% block custom_fields %}
{% endblock %}
{% endtag %}
```

This overrides the `custom_fields` block with an empty block so the default CKAN custom fields form does not render.

New in version 2.3: Starting from CKAN 2.3 you can combine free extras with custom fields handled with `convert_to_extras` and `convert_from_extras`. On prior versions you’ll always need to remove the free extras handling.

Next add a template in our template directory called `package/snippets/package_basic_fields.html` containing

```html
{% ckan_extends %}

{% if form.freetext %}
{% block custom_fields %}
{% endblock %}
{% endif %}
```

This overrides the `custom_fields` block with an empty block so the default CKAN custom fields form does not render.

New in version 2.3: Starting from CKAN 2.3 you can combine free extras with custom fields handled with `convert_to_extras` and `convert_from_extras`. On prior versions you’ll always need to remove the free extras handling.
This adds our custom_text field to the editing form. Finally we want to display our custom_text field on the dataset page. Add another file called package/snippets/additional_info.html containing

```html
{% ckan_extends %}
{% block extras %}
{% if pkg_dict.custom_text %}
<tr>
  <th scope="row" class="dataset-label">
    "Custom Text"
  </th>
  <td class="dataset-details">
    pkg_dict.custom_text
  </td>
</tr>
{% endif %}
{% endblock %}
{% endblock %}
```

This template overrides the default extras rendering on the dataset page and replaces it to just display our custom field.

You’re done! Make sure you have your plugin installed and setup as in the extension/tutorial. Then run a development server and you should now have an additional field called “Custom Text” when displaying and adding/editing a dataset.

**Cleaning up the code**

Before we continue further, we can clean up the `create_package_schema()` and `update_package_schema()` functions. There is a bit of duplication that we could remove. Replace the two functions with:

```python
def _modify_package_schema(self, schema):
schema.update({
    'custom_text': [tk.get_validator('ignore_missing'),
                   tk.get_converter('convert_to_extras')]
})
return schema

def create_package_schema(self):
schema = super(ExampleIDatasetFormPlugin, self).create_package_schema()
schema = self._modify_package_schema(schema)
return schema

def update_package_schema(self):
schema = super(ExampleIDatasetFormPlugin, self).update_package_schema()
schema = self._modify_package_schema(schema)
return schema
```
5.6.2 Custom validators

You may define custom validators in your extensions and you can share validators between extensions by registering them with the `IValidators` interface.

Any of the following objects may be used as validators as part of a custom dataset, group or organization schema. CKAN’s validation code will check for and attempt to use them in this order:

1. a formencode Validator class (not discussed)
2. a formencode Validator instance (not discussed)
3. a callable object taking a single parameter: `validator(value)`
4. a callable object taking four parameters: `validator(key, flattened_data, errors, context)`
5. a callable object taking two parameters `validator(value, context)`

**validator(value)**

The simplest form of validator is a callable taking a single parameter. For example:

```python
from ckan.plugins.toolkit import Invalid

def starts_with_b(value):
    if not value.startswith('b'):
        raise Invalid("Doesn't start with b")
    return value
```

The `starts_with_b` validator causes a validation error for values not starting with ‘b’. On a web form this validation error would appear next to the field to which the validator was applied.

`return value` must be used by validators when accepting data or the value will be converted to None. This form is useful for converting data as well, because the return value will replace the field value passed:

```python
def embiggen(value):
    return value.upper()
```

The `embiggen` validator will convert values passed to all-uppercase.

**validator(value, context)**

Validators that need access to the database or information about the user may be written as a callable taking two parameters. `context['session']` is the sqlalchemy session object and `context['user']` is the username of the logged-in user:

```python
from ckan.plugins.toolkit import Invalid

def fred_only(value, context):
    if value and context['user'] != 'fred':
        raise Invalid('only fred may set this value')
    return value
```

Otherwise this is the same as the single-parameter form above.
validator(key, flattened_data, errors, context)

Validators that need to access or update multiple fields may be written as a callable taking four parameters.

All fields and errors in a flattened form are passed to the validator. The validator must fetch values from flattened_data and may replace values in flattened_data. The return value from this function is ignored.

key is the flattened key for the field to which this validator was applied. For example ('notes',) for the dataset notes field or ('resources', 0, 'url') for the url of the first resource of the dataset. These flattened keys are the same in both the flattened_data and errors dicts passed.

errors contains lists of validation errors for each field.

context is the same value passed to the two-parameter form above.

Note that this form can be tricky to use because some of the values in flattened_data will have had validators applied but other fields won’t. You may add this type of validator to the special schema fields '__before' or '__after' to have them run before or after all the other validation takes place to avoid the problem of working with partially-validated data.

### 5.6.3 Tag vocabularies

If you need to add a custom field where the input options are restricted to a provided list of options, you can use tag vocabularies [Tag Vocabularies](https://docs.ckan.org/en/latest/dev-reference/schema-builder.html#tag-vocabularies). We will need to create our vocabulary first. By calling `vocabulary_create()`.

Add a function to your plugin.py above your plugin class.

```python
def create_country_codes():
    user = tk.get_action('get_site_user')({'ignore_auth': True}, {})
    context = {'user': user['name']}
    try:
        data = {'id': 'country_codes'}
        tk.get_action('vocabulary_show')(context, data)
    except tk.ObjectNotFound:
        data = {'name': 'country_codes'}
        vocab = tk.get_action('vocabulary_create')(context, data)
        for tag in (u'uk', u'ie', u'de', u'fr', u'es):
            data = {'name': tag, 'vocabulary_id': vocab['id']}
            tk.get_action('tag_create')(context, data)
```

This code block is taken from the example idatasetform plugin. `create_country_codes` tries to fetch the vocabulary country_codes using `vocabulary_show()`. If it is not found it will create it and iterate over the list of countries ‘uk’, ‘ie’, ‘de’, ‘fr’, ‘es’. For each of these a vocabulary tag is created using `tag_create()`, belonging to the vocabulary country_code.

Although we have only defined five tags here, additional tags can be created at any point by a sysadmin user by calling `tag_create()` using the API or action functions. Add a second function below `create_country_codes`.

```python
def country_codes():
    create_country_codes()
    try:
        tag_list = tk.get_action('tag_list')
        country_codes = tag_list(data_dict={'vocabulary_id': 'country_codes'})
        return country_codes
    except tk.ObjectNotFound:
        return None
```

country_codes will call `create_country_codes` so that the country_codes vocabulary is created if it does not exist. Then it calls `tag_list()` to return all of our vocabulary tags together. Now we have a way of retrieving...
our tag vocabularies and creating them if they do not exist. We just need our plugin to call this code.

Adding tags to the schema

Update _modify_package_schema() and show_package_schema()

```python
def _modify_package_schema(self, schema):
    schema.update(
        {'custom_text': [tk.get_validator('ignore_missing'),
                         tk.get_converter('convert_toExtras')]}
    )
schema.update({
    'country_code': [
        tk.get_validator('ignore_missing'),
        tk.get_converter('convert_to_tags')('country_codes')
    ]
    })
return schema

def show_package_schema(self):
    schema = super(ExampleIDatasetFormPlugin, self).show_package_schema()
    schema.update(
        {'custom_text': [tk.get_converter('convert_fromExtras'),
                         tk.get_validator('ignore_missing')]}
    )
schema['tags'][ '__extras' ].append(tk.get_converter('free_tags_only'))
schema.update({'country_code': [
    tk.get_converter('convert_from_tags')('country_codes'),
    tk.get_validator('ignore_missing')]
    })
return schema
```

We are adding our tag to our plugin’s schema. A converter is required to convert the field in to our tag in a similar way to how we converted our field to extras earlier. In show_package_schema() we convert from the tag back again but we have an additional line with another converter containing free_tags_only(). We include this line so that vocab tags are not shown mixed with normal free tags.

Adding tags to templates

Add an additional plugin.implements line to to your plugin to implement the ITemplateHelpers, we will need to add a get_helpers() function defined for this interface.

```python
p.implements(p.ITemplateHelpers)
def get_helpers(self):
    return {'country_codes': country_codes}
```

Our intention here is to tie our country_code fetching/creation to when they are used in the templates. Add the code below to package/snippets/package_metadata_fields.html

5.6. Customizing dataset and resource metadata fields using IDatasetForm
This adds our country code to our template, here we are using the additional helper country_codes that we defined in our get_helpers function in our plugin.

5.6.4 Adding custom fields to resources

In order to customize the fields in a resource the schema for resources needs to be modified in a similar way to the datasets. The resource schema is nested in the dataset dict as package['resources']. We modify this dict in a similar way to the dataset schema. Change _modify_package_schema to the following.

```python
def _modify_package_schema(self, schema):
    # Add our custom country_code metadata field to the schema.
    schema.update({
        'country_code': [tk.get_validator('ignore_missing'),
                         tk.get_converter('convert_to_tags')('country_codes')]
    })
    # Add our custom_test metadata field to the schema, this one will use
    # convert_to_extras instead of convert_to_tags.
    schema.update({
        'custom_text': [tk.get_validator('ignore_missing'),
                        tk.get_converter('convert_to_extras')]
    })
    # Add our custom_resource_text metadata field to the schema
    schema['resources'].update({
        'custom_resource_text': [tk.get_validator('ignore_missing')]
    })
    return schema
```

Update show_package_schema() similarly

```python
def show_package_schema(self):
    schema = super(ExampleIDatasetFormPlugin, self).show_package_schema()

    # Don't show vocab tags mixed in with normal 'free' tags
    # (e.g. on dataset pages, or on the search page)
    schema['tags'][('__extras').append(tk.get_converter('free_tags_only'))

(continues on next page)"
# Add our custom country_code metadata field to the schema.

```python
schema.update(
    'country_code': [tk.get_converter('convert_from_tags')('country_codes'),
                    tk.get_validator('ignore_missing')])
```

# Add our custom_text field to the dataset schema.

```python
schema.update({
    'custom_text': [tk.get_converter('convert_fromExtras'),
                    tk.get_validator('ignore_missing')]
})
```

```python
schema['resources'].update({
    'custom_resource_text': [tk.get_validator('ignore_missing')]
})
```

```python
return schema
```

Save and reload your development server CKAN will take any additional keys from the resource schema and save them its extras field. The templates will automatically check this field and display them in the resource_read page.

## 5.6.5 Sorting by custom fields on the dataset search page

Now that we’ve added our custom field, we can customize the CKAN web front end search page to sort datasets by our custom field. Add a new file called `ckanext-extrafields/ckanext/extrafields/templates/package/search.html` containing:

```html
{% ckan_extends %}

{% block form %}
{% set facets = {
    'fields': c.fields_grouped,
    'search': c.search_facets,
    'titles': c.facet_titles,
    'translated_fields': c.translated_fields,
    'remove_field': c.remove_field
} %}

{% set sorting = [
    ('Relevance'), 'score desc, metadata_modified desc',
    ('Name Ascending'), 'title_string asc',
    ('Name Descending'), 'title_string desc',
    ('Last Modified'), 'metadata_modified desc',
    ('Custom Field Ascending'), 'custom_text asc',
    ('Custom Field Descending'), 'custom_text desc',
    ('Popular'), 'views_recent desc' if g.tracking_enabled else (false, false) %]

{% snippet 'snippets/search_form.html', type='dataset', query=c.q, sorting=sorting, sorting_selected=c.sort_by_selected, count=c.page.item_count, facets=facets, show_empty=request.params, error=c.query_error %}
{% endblock %}
```

This overrides the search ordering drop down code block, the code is the same as the default dataset search block but we are adding two additional lines that define the display name of that search ordering (e.g. Custom Field Ascending) and the SOLR sort ordering (e.g. custom_text asc). If you reload your development server you should be able to see these two additional sorting options on the dataset search page.

### 5.6. Customizing dataset and resource metadata fields using IDatasetForm
The SOLR sort ordering can define arbitrary functions for custom sorting, but this is beyond the scope of this tutorial for further details see http://wiki.apache.org/solr/CommonQueryParameters#sort and http://wiki.apache.org/solr/FunctionQuery

You can find the complete source for this tutorial at https://github.com/ckan/ckan/tree/master/ckanext/example_idatasetform

### 5.7 Plugin interfaces reference

**ckan.plugins** contains a few core classes and functions for plugins to use:

```python
class ckan.plugins.SingletonPlugin(**kwargs)
    Base class for plugins which are singletons (ie most of them)
    One singleton instance of this class will be created when the plugin is loaded. Subsequent calls to the class
    constructor will always return the same singleton instance.

class ckan.plugins.Plugin(**kwargs)
    Base class for plugins which require multiple instances.
    Unless you need multiple instances of your plugin object you should probably use SingletonPlugin.

can.plugins.implements(interface, namespace=None, inherit=False, service=True)
    Can be used in the class definition of Plugin subclasses to declare the extension points that are implemented by
    this interface class.
    If the *inherits* option is True, then this Plugin class inherits from the *interface* class.
```

**ckan.plugins.interfaces**

A collection of interfaces that CKAN plugins can implement to customize and extend CKAN.

```python
class ckan.plugins.interfaces.Interface
    Base class for custom interfaces.
    Marker base class for extension point interfaces. This class is not intended to be instantiated. Instead, the
    declaration of subclasses of Interface are recorded, and these classes are used to define extension points.
    classmethod provided_by(instance)
        Check that object is an instance of class that implements interface.
    classmethod implemented_by(other)
        Check whether class implements current interface.

class ckan.plugins.interfaces.IMiddleware
    Hook into CKAN middleware stack
    Note that methods on this interface will be called two times, one for the Pylons stack and one for the Flask stack
    (eventually there will be only the Flask stack).
    make_middleware(app, config)
        Return an app configured with this middleware
        When called on the Flask stack, this method will get the actual Flask app so plugins wanting to install
        Flask extensions can do it like this:
```
import ckan.plugins as p
from flask_mail import Mail

class MyPlugin(p.SingletonPlugin):
    p.implements(p.I18nMiddleware)
    def make_middleware(app, config):
        mail = Mail(app)
        return app

make_error_log_middleware(app, config)
    Return an app configured with this error log middleware
    Note that both on the Flask and Pylons middleware stacks, this method will receive a wrapped WSGI app,
    not the actual Flask or Pylons app.
class ckan.plugins.interfaces.IRoutes
    Plugin into the setup of the routes map creation.
    before_map(map)
        Called before the routes map is generated. before_map is before any other mappings are created so can
        override all other mappings.
        Parameters map – Routes map object
        Returns Modified version of the map object
    after_map(map)
        Called after routes map is set up. after_map can be used to add fall-back handlers.
        Parameters map – Routes map object
        Returns Modified version of the map object
class ckan.plugins.interfaces.IMapper
    A subset of the SQLAlchemy mapper extension hooks. See sqlalchemy MapperExtension
    Example:
    >>> class MyPlugin(SingletonPlugin):
    ...    implements(IMapper)
    ...    def after_update(self, mapper, connection, instance):
    ...        log(u'Updated: %r', instance)

    before_insert(mapper, connection, instance)
        Receive an object instance before that instance is INSERTed into its table.
    before_update(mapper, connection, instance)
        Receive an object instance before that instance is UPDATEed.
    before_delete(mapper, connection, instance)
        Receive an object instance before that instance is PURGEd. (whereas usually in ckan ‘delete’ means to
        change the state property to deleted, so use before_update for that case.)
    after_insert(mapper, connection, instance)
        Receive an object instance after that instance is INSERTed.
after_update (mapper, connection, instance)
Receive an object instance after that instance is UPDATEed.

after_delete (mapper, connection, instance)
Receive an object instance after that instance is PURGEd. (whereas usually in ckan ‘delete’ means to change the state property to deleted, so use before_update for that case.)

class ckan.plugins.interfaces.ISession
A subset of the SQLAlchemy session extension hooks.

after_begin (session, transaction, connection)
Execute after a transaction is begun on a connection

before_flush (session, flush_context, instances)
Execute before flush process has started.

after_flush (session, flush_context)
Execute after flush has completed, but before commit has been called.

before_commit (session)
Execute right before commit is called.

after_commit (session)
Execute after a commit has occured.

after_rollback (session)
Execute after a rollback has occured.

class ckan.plugins.interfaces.IDomainObjectModification
Receives notification of new, changed and deleted datasets.

notify (entity, operation)
Send a notification on entity modification.

Parameters

• entity – instance of module.Package.
• operation – ‘new’, ‘changed’ or ‘deleted’.

notify_after_commit (entity, operation)
** DEPRECATED **
Supposed to send a notification after entity modification, but it doesn’t work.

Parameters

• entity – instance of module.Package.
• operation – ‘new’, ‘changed’ or ‘deleted’.

class ckan.plugins.interfaces.IFeed
Allows extension of the default Atom feeds

generate_feed ()
Allows plugins to provide a custom class to generate feed items.

Returns  feed class

Return type  type

The feed item generator’s constructor is called as follows:
feed_class(
    feed_title,       # Mandatory
    feed_link,        # Mandatory
    feed_description, # Mandatory
    language,         # Optional, always set to 'en'
    author_name,      # Optional
    author_link,      # Optional
    feed_guid,        # Optional
    feed_url,         # Optional
    previous_page,    # Optional, url of previous page of feed
    next_page,        # Optional, url of next page of feed
    first_page,       # Optional, url of first page of feed
    last_page         # Optional, url of last page of feed
)

get_item_additional_fields(dataset_dict)
Allows plugins to set additional fields on a feed item.

Parameters dataset_dict(dictionary) – the dataset metadata

Returns the fields to set

Return type dictionary

class ckan.plugins.interfaces.IResourceUrlChange
Receives notification of changed urls.

notify(resource)
    Give user a notify is resource url has changed.

:param resource, instance of model.Resource

class ckan.plugins.interfaces.IResourceView
Add custom view renderings for different resource types.

info()
Returns a dictionary with configuration options for the view.

The available keys are:

Parameters

- **name** – name of the view type. This should match the name of the actual plugin (eg image_view or recline_view).

- **title** – title of the view type, will be displayed on the frontend. This should be translat-
able (ie wrapped on toolkit._('Title')).

- **default_title** – default title that will be used if the view is created automatically (optional, defaults to 'View').

- **default_description** – default description that will be used if the view is created automatically (optional, defaults to '').

- **icon** – icon for the view type. Should be one of the Font Awesome types without the fa-
  fa- prefix eg. compass (optional, defaults to 'picture').

- **always_available** – the view type should be always available when creating new
  views regardless of the format of the resource (optional, defaults to False).

- **iframed** – the view template should be iframed before rendering. You generally want
  this option to be True unless the view styles and JavaScript don’t clash with the main site
  theme (optional, defaults to True).
• **preview_enabled** – the preview button should appear on the edit view form. Some view types have their previews integrated with the form (optional, defaults to False).

• **full_page_edit** – the edit form should take the full page width of the page (optional, defaults to False).

• **schema** – schema to validate extra configuration fields for the view (optional). Schemas are defined as a dictionary, with the keys being the field name and the values a list of validator functions that will get applied to the field. For instance:

```python
{
    'offset': [ignore_empty, natural_number_validator],
    'limit': [ignore_empty, natural_number_validator],
}
```

Example configuration object:

```python
{'name': 'image_view',
 'title': toolkit._('Image'),
 'schema': {
    'image_url': [ignore_empty, unicode]
 },
 'icon': 'picture-o',
 'always_available': True,
 'iframed': False,
}
```

Returns a dictionary with the view type configuration

Return type dict

**can_view**(data_dict)

Returns whether the plugin can render a particular resource.

The data_dict contains the following keys:

Parameters

• **resource** – dict of the resource fields

• **package** – dict of the full parent dataset

Returns True if the plugin can render a particular resource, False otherwise

Return type bool

**setup_template_variables**(context, data_dict)

Adds variables to be passed to the template being rendered.

This should return a new dict instead of updating the input data_dict.

The data_dict contains the following keys:

Parameters

• **resource_view** – dict of the resource view being rendered

• **resource** – dict of the parent resource fields

• **package** – dict of the full parent dataset

Returns a dictionary with the extra variables to pass

Return type dict
view_template(context, data_dict)

Returns a string representing the location of the template to be rendered when the view is displayed.

The path will be relative to the template directory you registered using the add_template_directory() on the update_config method, for instance views/my_view.html.

Parameters

• resource_view – dict of the resource view being rendered
• resource – dict of the parent resource fields
• package – dict of the full parent dataset

Returns the location of the view template.

Return type string

form_template(context, data_dict)

Returns a string representing the location of the template to be rendered when the edit view form is displayed.

The path will be relative to the template directory you registered using the add_template_directory() on the update_config method, for instance views/my_view_form.html.

Parameters

• resource_view – dict of the resource view being rendered
• resource – dict of the parent resource fields
• package – dict of the full parent dataset

Returns the location of the edit view form template.

Return type string

class ckan.plugins.interfaces.IResourcePreview

Warning: This interface is deprecated, and is only kept for backwards compatibility with the old resource preview code. Please use IResourceView for writing custom view plugins.

can_preview(data_dict)

Return info on whether the plugin can preview the resource.

This can be done in two ways:

1. The old way is to just return True or False.
2. The new way is to return a dict with three keys:

• can_preview(boolean) True if the extension can preview the resource.
• fixable (string) A string explaining how preview for the resource could be enabled, for example if the resource_proxy plugin was enabled.
• quality (int) How good the preview is: 1 (poor), 2 (average) or 3 (good). When multiple preview extensions can preview the same resource, this is used to determine which extension will be used.
Parameters **data_dict** (dictionary) – the resource to be previewed and the dataset that it belongs to.

Make sure to check the `on_same_domain` value of the resource or the url if your preview requires the resource to be on the same domain because of the same-origin policy. To find out how to preview resources that are on a different domain, read Resource Proxy.

**setup_template_variables** *(context, data_dict)*

Add variables to c just prior to the template being rendered. The `data_dict` contains the resource and the package.

Change the url to a proxied domain if necessary.

**preview_template** *(context, data_dict)*

Returns a string representing the location of the template to be rendered for the read page. The `data_dict` contains the resource and the package.

**class ckan.plugins.interfaces.ITagController**

Hook into the Tag controller. These will usually be called just before committing or returning the respective object, i.e. all validation, synchronization and authorization setup are complete.

**before_view** *(tag_dict)*

Extensions will receive this before the tag gets displayed. The dictionary passed will be the one that gets sent to the template.

**class ckan.plugins.interfaces.IGroupController**

Hook into the Group controller. These will usually be called just before committing or returning the respective object, i.e. all validation, synchronization and authorization setup are complete.

**read** *(entity)*

Called after IGroupController.before_view inside group_read.

**create** *(entity)*

Called after group had been created inside group_create.

**edit** *(entity)*

Called after group had been updated inside group_update.

**delete** *(entity)*

Called before commit inside group_delete.

**before_view** *(pkg_dict)*

Extensions will receive this before the group gets displayed. The dictionary passed will be the one that gets sent to the template.

**class ckan.plugins.interfaces.IOrganizationController**

Hook into the Organization controller. These will usually be called just before committing or returning the respective object, i.e. all validation, synchronization and authorization setup are complete.

**read** *(entity)*

Called after IOrganizationController.before_view inside organization_read.

**create** *(entity)*

Called after organization had been created inside organization_create.

**edit** *(entity)*

Called after organization had been updated inside organization_update.

**delete** *(entity)*

Called before commit inside organization_delete.
**before_view** *(pkg_dict)*
Extensions will receive this before the organization gets displayed. The dictionary passed will be the one that gets sent to the template.

**class** *ckan.plugins.interfaces.IPackageController*
Hook into the package controller. (see IGroupController)

**read**( *entity*)
Called after IGroupController.before_view inside package_read.

**create**( *entity*)
Called after group had been created inside package_create.

**edit**( *entity*)
Called after group had been updated inside package_update.

**delete**( *entity*)
Called before commit inside package_delete.

**after_create**( *context, pkg_dict*)
Extensions will receive the validated data dict after the package has been created (Note that the create method will return a package domain object, which may not include all fields). Also the newly created package id will be added to the dict.

**after_update**( *context, pkg_dict*)
Extensions will receive the validated data dict after the package has been updated (Note that the edit method will return a package domain object, which may not include all fields).

**after_delete**( *context, pkg_dict*)
Extensions will receive the data dict (tipically containing just the package id) after the package has been deleted.

**after_show**( *context, pkg_dict*)
Extensions will receive the validated data dict after the package is ready for display (Note that the read method will return a package domain object, which may not include all fields).

**before_search**( *search_params*)
Extensions will receive a dictionary with the query parameters, and should return a modified (or not) version of it.

search_params will include an *extras* dictionary with all values from fields starting with *ext_* , so extensions can receive user input from specific fields.

**after_search**( *search_results, search_params*)
Extensions will receive the search results, as well as the search parameters, and should return a modified (or not) object with the same structure:

```python
{'count': '', 'results': '', 'facets': ''}
```

Note that count and facets may need to be adjusted if the extension changed the results for some reason.

search_params will include an *extras* dictionary with all values from fields starting with *ext_* , so extensions can receive user input from specific fields.

**before_index**( *pkg_dict*)
Extensions will receive what will be given to the solr for indexing. This is essentially a flattened dict (except for multi-valued fields such as tags) of all the terms sent to the indexer. The extension can modify this by returning an altered version.

**before_view**( *pkg_dict*)
Extensions will receive this before the dataset gets displayed. The dictionary passed will be the one that gets sent to the template.

5.7. Plugin interfaces reference 231
class ckan.plugins.interfaces.IResourceController

Hook into the resource controller.

**before_create** *(context, resource)*

Extensions will receive this before a resource is created.

**Parameters**

- `context (dictionary)` – The context object of the current request, this includes for example access to the model and the user.
- `resource (dictionary)` – An object representing the resource to be added to the dataset (the one that is about to be created).

**after_create** *(context, resource)*

Extensions will receive this after a resource is created.

**Parameters**

- `context (dictionary)` – The context object of the current request, this includes for example access to the model and the user.
- `resource (dictionary)` – An object representing the latest resource added to the dataset (the one that was just created). A key in the resource dictionary worth mentioning is `url_type` which is set to `upload` when the resource file is uploaded instead of linked.

**before_update** *(context, current, resource)*

Extensions will receive this before a resource is updated.

**Parameters**

- `context (dictionary)` – The context object of the current request, this includes for example access to the model and the user.
- `current (dictionary)` – The current resource which is about to be updated
- `resource (dictionary)` – An object representing the updated resource which will replace the current one.

**after_update** *(context, resource)*

Extensions will receive this after a resource is updated.

**Parameters**

- `context (dictionary)` – The context object of the current request, this includes for example access to the model and the user.
- `resource (dictionary)` – An object representing the updated resource in the dataset (the one that was just updated). As with `after_create`, a noteworthy key in the resource dictionary is `url_type` which is set to `upload` when the resource file is uploaded instead of linked.

**before_delete** *(context, resource, resources)*

Extensions will receive this before a previously created resource is deleted.

**Parameters**

- `context (dictionary)` – The context object of the current request, this includes for example access to the model and the user.
- `resource (dictionary)` – An object representing the resource that is about to be deleted. This is a dictionary with one key: `id` which holds the `id` string of the resource that should be deleted.
• **resources** *(list)* – The list of resources from which the resource will be deleted (including the resource to be deleted if it existed in the package).

**after_delete** *(context, resources)*
Extensions will receive this after a previously created resource is deleted.

**Parameters**

• **context** *(dictionary)* – The context object of the current request, this includes for example access to the model and the user.

• **resources** – A list of objects representing the remaining resources after a resource has been removed.

**before_show** *(resource_dict)*
Extensions will receive the validated data dict before the resource is ready for display.

Be aware that this method is not only called for UI display, but also in other methods like when a resource is deleted because showing a package is used to get access to the resources in a package.

**class** ckan.plugins.interfaces.IPluginObserver
Plugin to the plugin loading mechanism

**before_load** *(plugin)*
Called before a plugin is loaded. This method is passed the plugin class.

**after_load** *(service)*
Called after a plugin has been loaded. This method is passed the instantiated service object.

**before_unload** *(plugin)*
Called before a plugin is unloaded. This method is passed the plugin class.

**after_unload** *(service)*
Called after a plugin has been unloaded. This method is passed the instantiated service object.

**class** ckan.plugins.interfaces.IConfigurer
Initialization hook for plugins.

See also **IConfigurer**.

**configure** *(config)*
Called during CKAN’s initialization.

This function allows plugins to initialize themselves during CKAN’s initialization. It is called after most of the environment (e.g. the database) is already set up.

Note that this function is not only called during the initialization of the main CKAN process but also during the execution of paster commands and background jobs, since these run in separate processes and are therefore initialized independently.

**Parameters** **config** *(ckan.common.ckanconfig)* – dict-like configuration object

**class** ckan.plugins.interfaces.IConfigurer
Configure CKAN environment via the **config** object

See also **IConfigurer**.

**update_config** *(config)*
Called by load_environment at earliest point when config is available to plugins. The config should be updated in place.

**Parameters** **config** – **config** object
update_config_schema(schema)

Return a schema with the runtime-editable config options

CKAN will use the returned schema to decide which configuration options can be edited during runtime (using ckan.logic.action.update.config_option_update()) and to validate them before storing them.

Defaults to ckan.logic.schema.default_update_configuration_schema(), which will be passed to all extensions implementing this method, which can add or remove runtime-editable config options to it.

Parameters schema (dictionary) – a dictionary mapping runtime-editable configuration option keys to lists of validator and converter functions to be applied to those keys

Returns a dictionary mapping runtime-editable configuration option keys to lists of validator and converter functions to be applied to those keys

Return type dictionary

class ckan.plugins.interfaces.IActions

Allow adding of actions to the logic layer.

get_actions()

Should return a dict, the keys being the name of the logic function and the values being the functions themselves.

By decorating a function with the ckan.logic.side_effect_free decorator, the associated action will be made available by a GET request (as well as the usual POST request) through the action API.

By decorating a function with the 'ckan.plugins.toolkit.chained_action, the action will be chained to another function defined in plugins with a “first plugin wins” pattern, which means the first plugin declaring a chained action should be called first. Chained actions must be defined as action_function(original_action, context, data_dict) where the first parameter will be set to the action function in the next plugin or in core ckan. The chained action may call the original_action function, optionally passing different values, handling exceptions, returning different values and/or raising different exceptions to the caller.

class ckan.plugins.interfaces.IValidators

Add extra validators to be returned by ckan.plugins.toolkit.get_validator().

get_validators()

Return the validator functions provided by this plugin.

Return a dictionary mapping validator names (strings) to validator functions. For example:

```python
{'valid_shoe_size': shoe_size_validator,
 'valid_hair_color': hair_color_validator}
```

These validator functions would then be available when a plugin calls ckan.plugins.toolkit.get_validator().

class ckan.plugins.interfaces.IAuthFunctions

Override CKAN’s authorization functions, or add new auth functions.

get_auth_functions()

Return the authorization functions provided by this plugin.

Return a dictionary mapping authorization function names (strings) to functions. For example:

```python
{'user_create': my_custom_user_create_function,
 'group_create': my_custom_group_create}
```
When a user tries to carry out an action via the CKAN API or web interface and CKAN or a CKAN plugin calls check_access('some_action') as a result, an authorization function named 'some_action' will be searched for in the authorization functions registered by plugins and in CKAN’s core authorization functions (found in ckan/logic/auth/).

For example when a user tries to create a package, a 'package_create' authorization function is searched for.

If an extension registers an authorization function with the same name as one of CKAN’s default authorization functions (as with 'user_create' and 'group_create' above), the extension’s function will override the default one.

Each authorization function should take two parameters context and data_dict, and should return a dictionary {'success': True} to authorize the action or {'success': False} to deny it, for example:

```python
def user_create(context, data_dict=None):
    if (some condition):
        return {'success': True}
    else:
        return {'success': False, 'msg': 'Not allowed to register'}
```

The context object will contain a model that can be used to query the database, a user containing the name of the user doing the request (or their IP if it is an anonymous web request) and an auth_user_obj containing the actual model.User object (or None if it is an anonymous request).

See ckan/logic/auth/ for more examples.

Note that by default, all auth functions provided by extensions are assumed to require a validated user or API key, otherwise a ckan.logic.NotAuthorized: exception will be raised. This check will be performed before calling the actual auth function. If you want to allow anonymous access to one of your actions, its auth function must be decorated with the auth_allow_anonymous_access decorator, available on the plugins toolkit.

For example:

```python
import ckan.plugins as p

@p.toolkit.auth_allow_anonymous_access
def my_search_action(context, data_dict):
    # Note that you can still return {'success': False} if for some
    # reason access is denied.

def my_create_action(context, data_dict):
    # Unless there is a logged in user or a valid API key provided
    # NotAuthorized will be raised before reaching this function.
```

By decorating a registered auth function with the 'ckan.plugins.toolkit.chained_auth_function' decorator you can create a chain of auth checks that are completed when auth is requested. This chain starts with the last chained auth function to be registered and ends with the original auth function (or a non-chained plugin override version). Chained auth functions must accept an extra parameter, specifically the next auth function in the chain, for example:

```python
auth_function(next_auth, context, data_dict).
```

The chained auth function may call the next_auth function, optionally passing different values, handling exceptions, returning different values and/or raising different exceptions to the caller.

```python
class ckan.plugins.interfaces.ITemplateHelpers
    Add custom template helper functions.
```
By implementing this plugin interface plugins can provide their own template helper functions, which custom templates can then access via the \texttt{h} variable.

See \texttt{ckanext/example_itemplatehelpers} for an example plugin.

\textbf{get_helpers()} \\
Return a dict mapping names to helper functions.

The keys of the dict should be the names with which the helper functions will be made available to templates, and the values should be the functions themselves. For example, a dict like:

\texttt{\{'example_helper': example_helper\}} allows templates to access the \texttt{example_helper} function via \texttt{h.example_helper()}.

Function names should start with the name of the extension providing the function, to prevent name clashes between extensions.

\textbf{class ckan.plugins.interfaces.IDatasetForm} \\
Customize CKAN's dataset (package) schemas and forms.

By implementing this interface plugins can customise CKAN's dataset schema, for example to add new custom fields to datasets.

Multiple IDatasetForm plugins can be used at once, each plugin associating itself with different package types using the \texttt{package_types()} and \texttt{is_fallback()} methods below, and then providing different schemas and templates for different types of dataset. When a package controller action is invoked, the \texttt{type} field of the package will determine which IDatasetForm plugin (if any) gets delegated to.

When implementing IDatasetForm, you can inherit from \texttt{ckan.plugins.toolkit.DefaultDatasetForm}, which provides default implementations for each of the methods defined in this interface.

See \texttt{ckanext/example_idatasetform} for an example plugin.

\textbf{package_types()} \\
Return an iterable of package types that this plugin handles.

If a request involving a package of one of the returned types is made, then this plugin instance will be delegated to.

There cannot be two IDatasetForm plugins that return the same package type, if this happens then CKAN will raise an exception at startup.

\textbf{Return type} iterable of strings

\textbf{is_fallback()} \\
Return \texttt{True} if this plugin is the fallback plugin.

When no IDatasetForm plugin's \texttt{package_types()} match the \texttt{type} of the package being processed, the fallback plugin is delegated to instead.

There cannot be more than one IDatasetForm plugin whose \texttt{is_fallback()} method returns \texttt{True}, if this happens CKAN will raise an exception at startup.

If no IDatasetForm plugin's \texttt{is_fallback()} method returns \texttt{True}, CKAN will use \texttt{DefaultDatasetForm} as the fallback.

\textbf{Return type} bool

\textbf{create_package_schema()} \\
Return the schema for validating new dataset dicts.

CKAN will use the returned schema to validate and convert data coming from users (via the dataset form or API) when creating new datasets, before entering that data into the database.
If it inherits from `ckan.plugins.toolkit.DefaultDatasetForm`, a plugin can call `DefaultDatasetForm.create_package_schema()` method to get the default schema and then modify and return it.

CKAN's `convert_to_tags()` or `convert_to_extras()` functions can be used to convert custom fields into dataset tags or extras for storing in the database.

See `ckanext/example_idatasetform` for examples.

**Returns**  a dictionary mapping dataset dict keys to lists of validator and converter functions to be applied to those keys

**Return type**  dictionary

**update_package_schema()**
Return the schema for validating updated dataset dicts.

CKAN will use the returned schema to validate and convert data coming from users (via the dataset form or API) when updating datasets, before entering that data into the database.

If it inherits from `ckan.plugins.toolkit.DefaultDatasetForm`, a plugin can call `DefaultDatasetForm.update_package_schema()` method to get the default schema and then modify and return it.

CKAN's `convert_to_tags()` or `convert_to_extras()` functions can be used to convert custom fields into dataset tags or extras for storing in the database.

See `ckanext/example_idatasetform` for examples.

**Returns**  a dictionary mapping dataset dict keys to lists of validator and converter functions to be applied to those keys

**Return type**  dictionary

**show_package_schema()**
Return a schema to validate datasets before they're shown to the user.

CKAN will use the returned schema to validate and convert data coming from the database before it is returned to the user via the API or passed to a template for rendering.

If it inherits from `ckan.plugins.toolkit.DefaultDatasetForm`, a plugin can call `DefaultDatasetForm.show_package_schema()` method to get the default schema and then modify and return it.

If you have used `convert_to_tags()` or `convert_to_extras()` in your `create_package_schema()` and `update_package_schema()` then you should use `convert_from_tags()` or `convert_from_extras()` in your `show_package_schema()` to convert the tags or extras in the database back into your custom dataset fields.

See `ckanext/example_idatasetform` for examples.

**Returns**  a dictionary mapping dataset dict keys to lists of validator and converter functions to be applied to those keys

**Return type**  dictionary

**setup_template_variables(context, data_dict)**
Add variables to the template context for use in templates.

This function is called before a dataset template is rendered. If you have custom dataset templates that require some additional variables, you can add them to the template context `ckan.plugins.toolkit.c` here and they will be available in your templates. See `ckanext/example_idatasetform` for an example.
new_template()
Return the path to the template for the new dataset page.
The path should be relative to the plugin’s templates dir, e.g. 'package/new.html'.

Return type  string

read_template()
Return the path to the template for the dataset read page.
The path should be relative to the plugin’s templates dir, e.g. 'package/read.html'.
If the user requests the dataset in a format other than HTML, then CKAN will try to render a template file with the same path as returned by this function, but a different filename extension, e.g. 'package/read.rdf'. If your extension (or another one) does not provide this version of the template file, the user will get a 404 error.

Return type  string

edit_template()
Return the path to the template for the dataset edit page.
The path should be relative to the plugin’s templates dir, e.g. 'package/edit.html'.

Return type  string

search_template()
Return the path to the template for use in the dataset search page.
This template is used to render each dataset that is listed in the search results on the dataset search page.
The path should be relative to the plugin’s templates dir, e.g. 'package/search.html'.

Return type  string

history_template()
Return the path to the template for the dataset history page.
The path should be relative to the plugin’s templates dir, e.g. 'package/history.html'.

Return type  string

resource_template()
Return the path to the template for the resource read page.
The path should be relative to the plugin’s templates dir, e.g. 'package/resource_read.html'.

Return type  string

package_form()
Return the path to the template for the dataset form.
The path should be relative to the plugin’s templates dir, e.g. 'package/form.html'.

Return type  string

resource_form()
Return the path to the template for the resource form.
The path should be relative to the plugin’s templates dir, e.g. 'package/snippets/resource_form.html'

Return type  string

validate(context, data_dict, schema, action)
Customize validation of datasets.
When this method is implemented it is used to perform all validation for these datasets. The default implementation calls and returns the result from `ckan.plugins.toolkit.navl_validate`.

This is an advanced interface. Most changes to validation should be accomplished by customizing the schemas returned from `show_package_schema()`, `create_package_schema()` and `update_package_schema()`. If you need to have a different schema depending on the user or value of any field stored in the dataset, or if you wish to use a different method for validation, then this method may be used.

**Parameters**

- `context` *(dictionary)* – extra information about the request
- `data_dict` *(dictionary)* – the dataset to be validated
- `schema` *(dictionary)* – a schema, typically from `show_package_schema()`, `create_package_schema()` or `update_package_schema()`
- `action` *(string)* – 'package_show', 'package_create' or 'package_update'

**Returns** *(data_dict, errors)* where `data_dict` is the possibly-modified dataset and `errors` is a dictionary with keys matching `data_dict` and lists-of-string-error-messages as values

**Return type** *(dictionary, dictionary)*

class ckan.plugins.interfaces.IGroupForm

Allows customisation of the group controller as a plugin.

The behaviour of the plugin is determined by 5 method hooks:

- `group_form(self)`
- `form_to_db_schema(self)`
- `db_to_form_schema(self)`
- `check_data_dict(self, data_dict)`
- `setup_template_variables(self, context, data_dict)`

Furthermore, there can be many implementations of this plugin registered at once. With each instance associating itself with 0 or more group type strings. When a group controller action is invoked, the group type determines which of the registered plugins to delegate to. Each implementation must implement two methods which are used to determine the group-type -> plugin mapping:

- `is_fallback(self)`
- `group_types(self)`
- `group_controller(self)`

Implementations might want to consider mixing in `ckan.lib.plugins.DefaultGroupForm` which provides default behaviours for the 5 method hooks.

**is_fallback()**

Returns true if this provides the fallback behaviour, when no other plugin instance matches a group’s type.

There must be exactly one fallback controller defined, any attempt to register more than one will throw an exception at startup. If there’s no fallback registered at startup the `ckan.lib.plugins.DefaultGroupForm` used as the fallback.

**group_types()**

Returns an iterable of group type strings.

If a request involving a group of one of those types is made, then this plugin instance will be delegated to.
There must only be one plugin registered to each group type. Any attempts to register more than one plugin instance to a given group type will raise an exception at startup.

**group_controller()**
Returns the name of the group controller.

The group controller is the controller, that is used to handle requests of the group type(s) of this plugin.

If this method is not provided, the default group controller is used (group).

**new_template()**
Returns a string representing the location of the template to be rendered for the ‘new’ page. Uses the default_group_type configuration option to determine which plugin to use the template from.

**index_template()**
Returns a string representing the location of the template to be rendered for the index page. Uses the default_group_type configuration option to determine which plugin to use the template from.

**read_template()**
Returns a string representing the location of the template to be rendered for the read page

**history_template()**
Returns a string representing the location of the template to be rendered for the history page

**edit_template()**
Returns a string representing the location of the template to be rendered for the edit page

**group_form()**
Returns a string representing the location of the template to be rendered. e.g. group/new_group_form.html.

**form_to_db_schema()**
Returns the schema for mapping group data from a form to a format suitable for the database.

**db_to_form_schema()**
Returns the schema for mapping group data from the database into a format suitable for the form (optional)

**check_data_dict(data_dict)**
Check if the return data is correct.
raise a DataError if not.

**setup_template_variables(context, data_dict)**
Add variables to c just prior to the template being rendered.

**validate(context, data_dict, schema, action)**
Customize validation of groups.

When this method is implemented it is used to perform all validation for these groups. The default implementation calls and returns the result from ckan.plugins.toolkit.navl_validate.

This is an advanced interface. Most changes to validation should be accomplished by customizing the schemas returned from form_to_db_schema() and db_to_form_schema(). If you need to have a different schema depending on the user or value of any field stored in the group, or if you wish to use a different method for validation, then this method may be used.

**Parameters**

- **context (dictionary)** – extra information about the request
- **data_dict (dictionary)** – the group to be validated
- **schema (dictionary)** – a schema, typically from form_to_db_schema(), or db_to_form_schema()
• **action** *(string)* – `'group_show'`, `'group_create'`, `'group_update'`, `'organization_show'`, `'organization_create'` or `'organization_update'`

**Returns** *(data_dict, errors)* where `data_dict` is the possibly-modified group and `errors` is a dictionary with keys matching `data_dict` and lists-of-string-error-messages as values

**Return type** *(dictionary, dictionary)*

class ckan.plugins.interfaces.IFacets

Customize the search facets shown on search pages.

By implementing this interface plugins can customize the search facets that are displayed for filtering search results on the dataset search page, organization pages and group pages.

The `facets_dict` passed to each of the functions below is an `OrderedDict` in which the keys are CKAN’s internal names for the facets and the values are the titles that will be shown for the facets in the web interface. The order of the keys in the dict determine the order that facets appear in on the page. For example:

```python
{'groups': _('Groups'),
 'tags': _('Tags'),
 'res_format': _('Formats'),
 'license': _('License'))
```

To preserve ordering, make sure to add new facets to the existing dict rather than updating it, ie do this:

```python
facets_dict['groups'] = p.toolkit._('Publisher')
facets_dict['secondary_publisher'] = p.toolkit._('Secondary Publisher')
```

rather than this:

```python
facets_dict.update({
    'groups': p.toolkit._('Publisher'),
    'secondary_publisher': p.toolkit._('Secondary Publisher'),
})
```

Dataset searches can be faceted on any field in the dataset schema that it makes sense to facet on. This means any dataset field that is in CKAN’s Solr search index, basically any field that you see returned by `package_show()`.

If there are multiple IFacets plugins active at once, each plugin will be called (in the order that they’re listed in the CKAN config file) and they will each be able to modify the facets dict in turn.

**dataset_facets**(facets_dict, package_type)

Modify and return the `facets_dict` for the dataset search page.

The `package_type` is the type of package that these facets apply to. Plugins can provide different search facets for different types of package. See IDatasetForm.

**Parameters**

• **facets_dict** *(OrderedDict)* – the search facets as currently specified

• **package_type** *(string)* – the package type that these facets apply to

**Returns** the updated `facets_dict`

**Return type** *OrderedDict*

group_facets*(facets_dict, group_type, package_type)*

Modify and return the `facets_dict` for a group’s page.
The `package_type` is the type of package that these facets apply to. Plugins can provide different search facets for different types of package. See `IDatasetForm`.

The `group_type` is the type of group that these facets apply to. Plugins can provide different search facets for different types of group. See `IGroupForm`.

Parameters

- `facets_dict` (OrderedDict) – the search facets as currently specified
- `group_type` (string) – the group type that these facets apply to
- `package_type` (string) – the package type that these facets apply to

Returns the updated `facets_dict`

Return type OrderedDict

`organization_facets(facets_dict, organization_type, package_type)`

Modify and return the `facets_dict` for an organization’s page.

The `package_type` is the type of package that these facets apply to. Plugins can provide different search facets for different types of package. See `IDatasetForm`.

The `organization_type` is the type of organization that these facets apply to. Plugins can provide different search facets for different types of organization. See `IGroupForm`.

Parameters

- `facets_dict` (OrderedDict) – the search facets as currently specified
- `organization_type` (string) – the organization type that these facets apply to
- `package_type` (string) – the package type that these facets apply to

Returns the updated `facets_dict`

Return type OrderedDict

`class ckan.plugins.interfaces.IAuthenticator`

Allows custom authentication methods to be integrated into CKAN.

`identify()`

called to identify the user.

If the user is identified then it should set c.user: The id of the user c.userobj: The actual user object (this may be removed as a requirement in a later release so that access to the model is not required)

`login()`

called at login.

`logout()`

called at logout.

`abort(status_code, detail, headers, comment)`

called on abort. This allows aborts due to authorization issues to be overridden

`class ckan.plugins.interfaces.ITranslation`

Allows extensions to provide their own translation strings.

`i18n_directory()`

Change the directory of the .mo translation files

`i18n_locales()`

Change the list of locales that this plugin handles
i18n_domain()
Change the gettext domain handled by this plugin

class ckan.plugins.interfaces.IUploader
Extensions implementing this interface can provide custom uploaders to upload resources and group images.

get_uploader(upload_to, old_filename)
Return an uploader object to upload general files that must implement the following methods:

__init__(upload_to, old_filename=None)
Set up the uploader.

Parameters

• upload_to(string) – name of the subdirectory within the storage directory to upload the file

• old_filename(string) – name of an existing image asset, so the extension can replace it if necessary

update_data_dict(data_dict, url_field, file_field, clear_field)
Allow the data_dict to be manipulated before it reaches any validators.

Parameters

• data_dict(dictionary) – data_dict to be updated

• url_field(string) – name of the field where the upload is going to be

• file_field(string) – name of the key where the FieldStorage is kept (i.e the field where the file data actually is).

• clear_field(string) – name of a boolean field which requests the upload to be deleted.

upload(max_size)
Perform the actual upload.

Parameters max_size(int) – upload size can be limited by this value in MBs.

get_resource_uploader()
Return an uploader object used to upload resource files that must implement the following methods:

__init__(resource)
Set up the resource uploader.

Parameters resource(dictionary) – resource dict

Optionally, this method can set the following two attributes on the class instance so they are set in the resource object:

upload(id, max_size)
Perform the actual upload.

Parameters

• id(string) – resource id, can be used to create filepath

• max_size(int) – upload size can be limited by this value in MBs.
get_path(id)

Required by the resource_download action to determine the path to the file.

Parameters id (string) – resource id

class ckan.plugins.interfaces.IBlueprint
    Register an extension as a Flask Blueprint.

get_blueprint()
    Return a Flask Blueprint object to be registered by the app.

class ckan.plugins.interfaces.IPermissionLabels
    Extensions implementing this interface can override the permission labels applied to datasets to precisely control which datasets are visible to each user.

    Implementations might want to consider mixing in ckan.lib.plugins.DefaultPermissionLabels which provides default behaviours for these methods.

    See ckanext/example_ipermissionlabels for an example plugin.

get_dataset_labels(dataset_obj)
    Return a list of unicode strings to be stored in the search index as the permission labels for a dataset dict.

    Parameters dataset_obj (Package model object) – dataset details

    Returns permission labels

    Return type list of unicode strings

get_user_dataset_labels(user_obj)
    Return the permission labels that give a user permission to view a dataset. If any of the labels returned from this method match any of the labels returned from get_dataset_labels() then this user is permitted to view that dataset.

    Parameters user_obj (User model object or None) – user details

    Returns permission labels

    Return type list of unicode strings

class ckan.plugins.interfaces.IForkObserver
    Observe forks of the CKAN process.

    before_fork()
    Called shortly before the CKAN process is forked.

5.8 Plugins toolkit reference

As well as using the variables made available to them by implementing plugin interfaces, plugins will likely want to be able to use parts of the CKAN core library. To allow this, CKAN provides a stable set of classes and functions that plugins can use safe in the knowledge that this interface will remain stable, backward-compatible and with clear deprecation guidelines when new versions of CKAN are released. This interface is available in CKAN’s plugins toolkit.

class ckan.plugins.toolkit.BaseController
    Base class for CKAN controller classes to inherit from.

class ckan.plugins.toolkit.CkanCommand
    Base class for classes that implement CKAN paster commands to inherit.
class ckan.plugins.toolkit.CkanVersionException
Exception raised by requires_ckan_version() if the required CKAN version is not available.

class ckan.plugins.toolkit.DefaultDatasetForm
The default implementation of IDatasetForm.

This class serves two purposes:

1. It provides a base class for plugin classes that implement IDatasetForm to inherit from, so they can inherit the default behavior and just modify the bits they need to.

2. It is used as the default fallback plugin when no registered IDatasetForm plugin handles the given dataset type and no other plugin has registered itself as the fallback plugin.

Note: DefaultDatasetForm doesn’t call implements(), because we don’t want it being registered.

class ckan.plugins.toolkit.DefaultGroupForm
Provides a default implementation of the pluggable Group controller behaviour.

This class has 2 purposes:

• it provides a base class for IGroupForm implementations to use if only a subset of the method hooks need to be customised.

• it provides the fallback behaviour if no plugin is setup to provide the fallback behaviour.

Note - this isn’t a plugin implementation. This is deliberate, as we don’t want this being registered.

class ckan.plugins.toolkit.DefaultOrganizationForm

class ckan.plugins.toolkit.HelperError
Raised if an attempt to access an undefined helper is made.

Normally, this would be a subclass of AttributeError, but Jinja2 will catch and ignore them. We want this to be an explicit failure re #2908.

class ckan.plugins.toolkit.Invalid
Exception raised by some validator, converter and dictization functions when the given value is invalid.

class ckan.plugins.toolkit.NotAuthorized
Exception raised when the user is not authorized to call the action.

For example package_create() raises NotAuthorized if the user is not authorized to create packages.

class ckan.plugins.toolkit.ObjectNotFound
Exception raised by logic functions when a given object is not found.

For example package_show() raises ObjectNotFound if no package with the given id exists.

class ckan.plugins.toolkit.StopOnError
error to stop validations for a particular key

class ckan.plugins.toolkit.UnknownValidator
Exception raised when a requested validator function cannot be found.

class ckan.plugins.toolkit.ValidationException
Exception raised by action functions when validating their given data_dict fails.

ckan.plugins.toolkit._(*args, **kwargs)
Translates a string to the current locale.
The \_() function is a reference to the ugettext() function. Everywhere in your code where you want strings to be internationalized (made available for translation into different languages), wrap them in the \_() function, eg.:

```python
msg = toolkit._("Hello")
```

Returns the localized unicode string.

**ckan.plugins.toolkit.abort**(status_code=None, detail=", headers=None, comment=None)

Abort the current request immediately by returning an HTTP exception.

This is a wrapper for pylons.controllers.util.abort() that adds some CKAN custom behavior, including allowing IAuthenticator plugins to alter the abort response, and showing flash messages in the web interface.

**ckan.plugins.toolkit.add_ckan_admin_tab**(cls, config, route_name, tab_label, config_var='ckan.admin_tabs')

Update ‘ckan.admin_tabs’ dict the passed config dict.

**ckan.plugins.toolkit.add_public_directory**(cls, config, relative_path)

Add a path to the extra_public_paths config setting.

The path is relative to the file calling this function.

**ckan.plugins.toolkit.add_resource**(cls, path, name)

Add a Fanstatic resource library to CKAN.

Fanstatic libraries are directories containing static resource files (e.g. CSS, JavaScript or image files) that can be accessed from CKAN.

See Theming guide for more details.

**ckan.plugins.toolkit.add_template_directory**(cls, config, relative_path)

Add a path to the extra_template_paths config setting.

The path is relative to the file calling this function.

**ckan.plugins.toolkit.asbool**(obj)

Convert a string (e.g. 1, true, True) from the config file into a boolean.

For example: if toolkit.asbool(config.get('ckan.legacy_templates', False)):

**ckan.plugins.toolkit.asint**(obj)

Convert a string from the config file into an int.

For example: bar = toolkit.asint(config.get('ckan.foo.bar', 0))

**ckan.plugins.toolkit.aslist**(obj, sep=None, strip=True)

Convert a space-separated string from the config file into a list.

For example: bar = toolkit.aslist(config.get('ckan.foo.bar', []))

**ckan.plugins.toolkit.auth_allow_anonymous_access**(action)

Flag an auth function as not requiring a logged in user

This means that check_access won’t automatically raise a NotAuthorized exception if an authenticated user is not provided in the context. (The auth function can still return False if for some reason access is not granted).

**ckan.plugins.toolkit.auth_disallow_anonymous_access**(action)

Flag an auth function as requiring a logged in user

This means that check_access will automatically raise a NotAuthorized exception if an authenticated user is not provided in the context, without calling the actual auth function.
ckan.plugins.toolkit.auth_sysadmins_check(action)
A decorator that prevents sysadmins from being automatically authorized to call an action function.

Normally sysadmins are allowed to call any action function (for example when they’re using the Action API or the web interface), if the user is a sysadmin the action function’s authorization function will not even be called.

If an action function is decorated with this decorator, then its authorization function will always be called, even if the user is a sysadmin.

ckan.plugins.toolkit.c
The Pylons template context object.

[Deprecated]: Use toolkit.g instead.

This object is used to pass request-specific information to different parts of the code in a thread-safe way (so that variables from different requests being executed at the same time don’t get confused with each other).

Any attributes assigned to c are available throughout the template and application code, and are local to the current request.

ckan.plugins.toolkit.chained_action(func)
ckan.plugins.toolkit.chained_auth_function(func)
Decorator function allowing authentication functions to be chained.

ckan.plugins.toolkit.check_access(action, context, data_dict=None)
Calls the authorization function for the provided action

This is the only function that should be called to determine whether a user (or an anonymous request) is allowed to perform a particular action.

The function accepts a context object, which should contain a ‘user’ key with the name of the user performing the action, and optionally a dictionary with extra data to be passed to the authorization function.

For example:

```
check_access('package_update', context, data_dict)
```

If not already there, the function will add an auth_user_obj key to the context object with the actual User object (in case it exists in the database). This check is only performed once per context object.

Raise NotAuthorized if the user is not authorized to call the named action function.

If the user is authorized to call the action, return True.

Parameters

• action(string) – the name of the action function, eg. 'package_create'

• context(dict)–

• data_dict(dict)–

Raising NotAuthorized if the user is not authorized to call the named action

ckan.plugins.toolkit.check_ckan_version(cls, min_version=None, max_version=None)
Return True if the CKAN version is greater than or equal to min_version and less than or equal to max_version, return False otherwise.

If no min_version is given, just check whether the CKAN version is less than or equal to max_version.
If no max_version is given, just check whether the CKAN version is greater than or equal to min_version.

Parameters

• min_version(string) – the minimum acceptable CKAN version, eg. '2.1'
**max_version**(string) – the maximum acceptable CKAN version, eg. '2.3'

ckan.plugins.toolkit.config

The CKAN configuration object.

It stores the configuration values defined in the CKAN configuration file, eg:

```python
title = toolkit.config.get("ckan.site_title")
```

ckan.plugins.toolkit.enqueue_job(fn, args=None, kwargs=None, title=None, queue=u'default', rq_kwargs=None)

Enqueue a job to be run in the background.

**Parameters**

- **fn**(function) – Function to be executed in the background
- **args**(list) – List of arguments to be passed to the function. Pass an empty list if there are no arguments (default).
- **kwargs**(dict) – Dict of keyword arguments to be passed to the function. Pass an empty dict if there are no keyword arguments (default).
- **title**(string) – Optional human-readable title of the job.
- **queue**(string) – Name of the queue. If not given then the default queue is used.
- **rq_kwargs**(dict) – Dict of keyword arguments that will get passed to the RQ enqueue_call invocation (eg timeout, depends_on, ttl etc).

**Returns** The enqueued job.

**Return type** rq.job.Job

ckan.plugins.toolkit.g

The Flask global object.

This object is used to pass request-specific information to different parts of the code in a thread-safe way (so that variables from different requests being executed at the same time don’t get confused with each other).

Any attributes assigned to \( g \) are available throughout the template and application code, and are local to the current request (Note that \( g \) won’t be available on templates rendered by old endpoints served by Pylons).

It is a bad pattern to pass variables to the templates using the \( g \) object. Pass them explicitly from the view functions as `extra_vars`, eg:

```python
return toolkit.render('myext/package/read.html',
    extra_vars={
        u'some_var': some_value,
        u'some_other_var': some_other_value,
    })
```

ckan.plugins.toolkit.get_action(action)

Return the named ckan.logic.action function.

For example `get_action('package_create')` will normally return the `ckan.logic.action.create.package_create()` function.

For documentation of the available action functions, see Action API reference.
You should always use `get_action()` instead of importing an action function directly, because `IActions` plugins can override action functions, causing `get_action()` to return a plugin-provided function instead of the default one.

Usage:

```python
import ckan.plugins.toolkit as toolkit

# Call the package_create action function:
toolkit.get_action('package_create')(context, data_dict)
```

As the context parameter passed to an action function is commonly:

```python
context = {'model': ckan.model, 'session': ckan.model.Session, 'user': pylons.c.user}
```

an action function returned by `get_action()` will automatically add these parameters to the context if they are not defined. This is especially useful for plugins as they should not really be importing parts of ckan eg `ckan.model` and as such do not have access to `model` or `model.Session`.

If a `context` of `None` is passed to the action function then the default context dict will be created.

**Note:** Many action functions modify the context dict. It can therefore not be reused for multiple calls of the same or different action functions.

### Parameters

- **action** *(string)* – name of the action function to return, eg. `'package_create'`
- **Returns** the named action function
- **Return type** callable

### Parameters

- **validator** *(string)* – the name of the validator function to return, eg. `'package_name_exists'`
- **Raises** `UnknownValidator` if the named validator is not found
- **Returns** the named validator function
- **Return type** `types.FunctionType`

### Returns tuple in format: (controller|blueprint, action|view).

### Return the value(s) from the given data_dict for the given key(s).

#### Parameters

- **data_dict** *(dictionary)* – the dictionary to return the values from
- **keys** *(either a string or a list)* – the key(s) for the value(s) to return

5.8. Plugins toolkit reference
Returns a single value from the dict if a single key was given, or a tuple of values if a list of keys was given

Raises ckan.logic.ValidationError if one of the given keys is not in the given dictionary

ckan.plugins.toolkit.get_validator(validator)
Return a validator function by name.

Parameters validator (string) – the name of the validator function to return, eg. 'package_name_exists'

Raises UnknownValidator if the named validator is not found

Returns the named validator function

Return type types.FunctionType

ckan.plugins.toolkit.literal

This subclass of unicode has a __html__() method that is detected by the escape() function.

Also, if you add another string to this string, the other string will be quoted and you will get back another literal object. Also literal(...) % obj will quote any value(s) from obj. If you do something like literal(...) + literal(...), neither string will be changed because escape(literal(...)) doesn’t change the original literal.

Changed in WebHelpers 1.2: the implementation is now now a subclass of markupsafe.Markup. This brings some new methods: escape (class method), .unescape, and .striptags.

ckan.plugins.toolkit.load_config(config, load_site_user=True)

ckan.plugins.toolkit.missing

ckan.plugins.toolkit.navl_validate(data, schema, context=None)

Validate an unflattened nested dict against a schema.

ckan.plugins.toolkit.redirect_to(*args, **kw)

Issue a redirect: return an HTTP response with a 302 Moved header.

This is a wrapper for routes.redirect_to() that maintains the user’s selected language when redirecting.

The arguments to this function identify the route to redirect to, they’re the same arguments as ckan.plugins.toolkit.url_for() accepts, for example:

```
import ckan.plugins.toolkit as toolkit

# Redirect to /dataset/my_dataset.
toolkit.redirect_to(controller='package', action='read',
    id='my_dataset')
```

Or, using a named route:

```
toolkit.redirect_to('dataset_read', id='changed')
```

If given a single string as argument, this redirects without url parsing

```
toolkit.redirect_to('http://example.com')
toolkit.redirect_to('/dataset')
toolkit.redirect_to('/some/other/path')
```
ckan.plugins.toolkit.render\(\text{template\_name, extra\_vars=None, *pargs, **kwargs}\)

Render a template and return the output.

This is CKAN’s main template rendering function.

- **Params template\_name** relative path to template inside registered tpl\_dir
- **Params extra\_vars** additional variables available in template
- **Params pargs** DEPRECATED
- **Params kwargs** DEPRECATED

ckan.plugins.toolkit.render\_snippet\(\text{cls, template, data=None}\)

Render a template snippet and return the output.

See Theming guide.

ckan.plugins.toolkit.request

The Pylons request object.

A new request object is created for each HTTP request. It has methods and attributes for getting things like the request headers, query-string variables, request body variables, cookies, the request URL, etc.

ckan.plugins.toolkit.requires\_ckan\_version\(\text{cls, min\_version, max\_version=\text{None}}\)

Raise CkanVersionException if the CKAN version is not greater than or equal to min\_version and less then or equal to max\_version.

If no max\_version is given, just check whether the CKAN version is greater than or equal to min\_version.

Plugins can call this function if they require a certain CKAN version, other versions of CKAN will crash if a user tries to use the plugin with them.

- **Parameters**
  - **min\_version** (\text{string}) – the minimum acceptable CKAN version, eg. '2.1'
  - **max\_version** (\text{string}) – the maximum acceptable CKAN version, eg. '2.3'

ckan.plugins.toolkit.response

The Pylons response object.

Pylons uses this object to generate the HTTP response it returns to the web browser. It has attributes like the HTTP status code, the response headers, content type, cookies, etc.

ckan.plugins.toolkit.side\_effect\_free\(\text{action}\)

A decorator that marks the given action function as side-effect-free.

Action functions decorated with this decorator can be called with an HTTP GET request to the Action API. Action functions that don’t have this decorator must be called with a POST request.

If your CKAN extension defines its own action functions using the IActions plugin interface, you can use this decorator to make your actions available with GET requests instead of just with POST requests.

Example:

```python
import ckan.plugins.toolkit as toolkit

@toolkit.side_effect_free
def my_custom_action_function(context, data_dict):
    ...
```

(Then implement IActions to register your action function with CKAN.)
ckan.plugins.toolkit.ungettext(*args, **kwargs)

Translates a string with plural forms to the current locale.

Mark a string for translation that has plural forms in the format ungettext(singular, plural, n).
Returns the localized unicode string of the pluralized value.

Mark a string to be localized as follows:

```python
msg = toolkit.ungettext("Mouse", "Mice", len(mouses))
```

ckan.plugins.toolkit.url_for(*args, **kw)

Return the URL for an endpoint given some parameters.

This is a wrapper for flask.url_for() and routes.url_for() that adds some extra features that CKAN needs.

To build a URL for a Flask view, pass the name of the blueprint and the view function separated by a period.,
plus any URL parameters:

```python
url_for('api.action', ver=3, logic_function='status_show')
# Returns /api/3/action/status_show
```

For a fully qualified URL pass the _external=True parameter. This takes the ckan.site_url and
ckan.root_path settings into account:

```python
url_for('api.action', ver=3, logic_function='status_show',
    _external=True)
# Returns http://example.com/api/3/action/status_show
```

URLs built by Pylons use the Routes syntax:

```python
url_for(controller='package', action='read', id='my_dataset')
# Returns '/dataset/my_dataset'
```

Or, using a named route:

```python
url_for('dataset_read', id='changed')
# Returns '/dataset/changed'
```

Use qualified=True for a fully qualified URL when targeting a Pylons endpoint.

For backwards compatibility, an effort is made to support the Pylons syntax when building a Flask URL, but
this support might be dropped in the future, so calls should be updated.

### 5.9 Validator functions reference

ckan.logic.validators.owner_org_validator(key, data, errors, context)

ckan.logic.validators.package_id_not_changed(value, context)

ckan.logic.validators.int_validator(value, context)

   Return an integer for value, which may be a string in base 10 or a numeric type (e.g. int, long, float, Decimal, Fraction). Return None for None or empty/all-whitespace string values.

   Raises ckan.lib.navl.dictization_functions.Invalid for other inputs or non-whole values

ckan.logic.validators.natural_number_validator(value, context)

ckan.logic.validators.is_positive_integer(value, context)
ckan.logic.validators.boolean_validator(value, context)
   Return a boolean for value. Return value when value is a python bool type. Return True for strings 'true', 'yes', 't', 'y', and '1'. Return False in all other cases, including when value is an empty string or None

ckan.logic.validators.isodate(value, context)

ckan.logic.validators.no_http(value, context)

ckan.logic.validators.package_id_exists(value, context)

ckan.logic.validators.package_id_does_not_exist(value, context)

ckan.logic.validators.package_name_exists(value, context)

ckan.logic.validators.package_id_or_name_exists(package_id_or_name, context)
   Return the given package_id_or_name if such a package exists.

   Raises ckan.lib.navl.dictization_functions.Invalid if there is no package with the given id or name

ckan.logic.validators.resource_id_exists(value, context)

ckan.logic.validators.user_id_exists(user_id, context)
   Raises Invalid if the given user_id does not exist in the model given in the context, otherwise returns the given user_id.

ckan.logic.validators.user_id_or_name_exists(user_id_or_name, context)
   Return the given user_id_or_name if such a user exists.

   Raises ckan.lib.navl.dictization_functions.Invalid if no user can be found with the given id or user name

ckan.logic.validators.group_id_exists(group_id, context)
   Raises Invalid if the given group_id does not exist in the model given in the context, otherwise returns the given group_id.

ckan.logic.validators.group_id_or_name_exists(reference, context)
   Raises Invalid if a group identified by the name or id cannot be found.

ckan.logic.validators.activity_type_exists(activity_type)
   Raises Invalid if there is no registered activity renderer for the given activity_type. Otherwise returns the given activity_type.

   This just uses object_id_validators as a lookup. very safe.

ckan.logic.validators.object_id_validator(key, activity_dict, errors, context)
   Validate the ‘object_id’ value of an activity_dict.

   Uses the object_id_validators dict (above) to find and call an ‘object_id’ validator function for the given activity_dict’s ‘activity_type’ value.

   Raises Invalid if the model given in context contains no object of the correct type (according to the ‘activity_type’ value of the activity_dict) with the given ID.

   Raises Invalid if there is no object_id_validator for the activity_dict’s ‘activity_type’ value.

ckan.logic.validators.name_validator(value, context)
   Return the given value if it’s a valid name, otherwise raise Invalid.

   If it’s a valid name, the given value will be returned unmodified.

   This function applies general validation rules for names of packages, groups, users, etc.

   Most schemas also have their own custom name validator function to apply custom validation rules after this function, for example a package_name_validator() to check that no package with the given name already exists.

5.9. Validator functions reference 253
Raises ckan.lib.navl.dictization_functions.Invalid – if value is not a valid name

ckan.logic.validators.package_name_validator(key, data, errors, context)
ckan.logic.validators.package_version_validator(value, context)
ckan.logic.validators.duplicate_extras_key(key, data, errors, context)
ckan.logic.validators.group_name_validator(key, data, errors, context)
ckan.logic.validators.tag_length_validator(value, context)
ckan.logic.validators.tag_name_validator(value, context)
ckan.logic.validators.tag_not_uppercase(value, context)
ckan.logic.validators.tag_string_convert(key, data, errors, context)
ckan.logic.validators.ignore_not_admin(key, data, errors, context)
ckan.logic.validators.ignore_not_package_admin(key, data, errors, context)
  Ignore if the user is not allowed to administer the package specified.
ckan.logic.validators.ignore_not_sysadmin(key, data, errors, context)
  Ignore the field if user not sysadmin or ignore_auth in context.
ckan.logic.validators.ignore_not_group_admin(key, data, errors, context)
  Ignore if the user is not allowed to administer for the group specified.
ckan.logic.validators.user_name_validator(key, data, errors, context)
  Validate a new user name.
    Append an error message to errors[key] if a user named data[key] already exists. Otherwise, do nothing.
    Raises ckan.lib.navl.dictization_functions.Invalid – if data[key] is not a string

Return type None

ckan.logic.validators.user_both_passwords_entered(key, data, errors, context)
ckan.logic.validators.user_password_validator(key, data, errors, context)
ckan.logic.validators.user_passwords_match(key, data, errors, context)
ckan.logic.validators.user_password_not_empty(key, data, errors, context)
  Only check if password is present if the user is created via action API. If not, user_both_passwords_entered will handle the validation
ckan.logic.validators.user_about_validator(value, context)
ckan.logic.validators.vocabulary_name_validator(name, context)
ckan.logic.validators.vocabulary_id_not_changed(value, context)
ckan.logic.validators.vocabulary_id_exists(value, context)
ckan.logic.validators.tag_in_vocabulary_validator(value, context)
ckan.logic.validators.tag_not_in_vocabulary(key, tag_dict, errors, context)
ckan.logic.validators.url_validator(key, data, errors, context)
  Checks that the provided value (if it is present) is a valid URL
ckan.logic.validators.user_name_exists(user_name, context)
ckan.logic.validators.role_exists(role, context)
ckan.logic.validators.datasets_with_no_organization_cannot_be_private(key, data, errors, context)
ckan.logic.validators.list_of_strings(key, data, errors, context)
ckan.logic.validators.if_empty_guess_format(key, data, errors, context)
ckan.logic.validators.clean_format(format)
ckan.logic.validators.no_loops_in_hierarchy(key, data, errors, context)
    Checks that the parent groups specified in the data would not cause a loop in the group hierarchy, and therefore cause the recursion up/down the hierarchy to get into an infinite loop.
ckan.logic.validators.filter_fields_and_values_should_have_same_length(key, data, errors, context)
ckan.logic.validators.filter_fields_and_values_exist_and_are_valid(key, data, errors, context)
ckan.logic.validators.extra_key_not_in_root_schema(key, data, errors, context)
ckan.logic.validators.empty_if_not_sysadmin(key, data, errors, context)
    Only sysadmins may pass this value
ckan.logic.validators.email_validator(value, context)
    Validate email input
ckan.logic.validators.email_is_unique(key, data, errors, context)
    Validate email is unique
ckan.logic.validators.one_of(list_of_value)
    Checks if the provided value is present in a list
ckan.logic.validators.json_object(value)
    Make sure value can be serialized as a JSON object
ckan.logic.validators.extras_valid_json(extras, context)
ckan.logic.converters.convert_to_extras(key, data, errors, context)
ckan.logic.converters.convert_from_extras(key, data, errors, context)
ckan.logic.converters.extras_unicode_convert(extras, context)
ckan.logic.converters.free_tags_only(key, data, errors, context)
ckan.logic.converters.convert_to_tags(vocab)
ckan.logic.converters.convert_from_tags(vocab)
ckan.logic.converters.convert_user_name_or_id_to_id(user_name_or_id, context)
    Return the user id for the given user name or id.

5.9. Validator functions reference 255
The point of this function is to convert user names to ids. If you have something that may be a user name or a user id you can pass it into this function and get the user id out either way.

Also validates that a user with the given name or id exists.

Returns the id of the user with the given user name or id

Return type string

Raises ckan.lib.navl.dictization_functions.Invalid if no user can be found with the given id or user name

ckan.logic.converters.convert_package_name_or_id_to_id(package_name_or_id, context)

Return the package id for the given package name or id.

The point of this function is to convert package names to ids. If you have something that may be a package name or id you can pass it into this function and get the id out either way.

Also validates that a package with the given name or id exists.

Returns the id of the package with the given name or id

Return type string

Raises ckan.lib.navl.dictization_functions.Invalid if there is no package with the given name or id

ckan.logic.converters.convert_group_name_or_id_to_id(group_name_or_id, context)

Return the group id for the given group name or id.

The point of this function is to convert group names to ids. If you have something that may be a group name or id you can pass it into this function and get the id out either way.

Also validates that a group with the given name or id exists.

Returns the id of the group with the given name or id

Return type string

Raises ckan.lib.navl.dictization_functions.Invalid if there is no group with the given name or id

ckan.logic.converters.convert_to_json_if_string(value, context)
ckan.logic.converters.convert_to_list_if_string(value, context=None)
ckan.logic.converters.remove_whitespace(value, context)

5.10 Internationalizing strings in extensions

See also:

In order to internationalize your extension you must mark its strings for internationalization. See also Translating CKAN.

This tutorial assumes that you have read the Writing extensions tutorial.

We will create a simple extension to demonstrate the translation of strings inside extensions. After running:

```
paster --plugin=ckan create -t ckanext ckanext-itranslation
```

Change the plugin.py file to:
```python
# encoding: utf-8
from ckan import plugins
from ckan.plugins import toolkit

class ExampleITranslationPlugin(plugins.SingletonPlugin):
    plugins.implements(plugins.IConfigurer)
    def update_config(self, config):
        toolkit.add_template_directory(config, 'templates')
```

Add a template file `ckanext-itranslation/templates/home/index.html` containing:

```html
{% ckan_extends %}
{% block primary_content %}
{% trans %}This is an untranslated string{% endtrans %}
{% endblock %}
```

This template provides a sample string that we will internationalize in this tutorial.

**Note:** While this tutorial only covers Python/Jinja templates it is also possible (since CKAN 2.7) to translate strings in an extension’s JavaScript modules.

**5.10.1 Extract strings**

**Tip:** If you have generated a new extension whilst following this tutorial the default template will have generated these files for you and you can simply run the `extract_messages` command immediately.

Check your `setup.py` file in your extension for the following lines:

```python
setup(
    entry_points='',
    [ckan.plugins]
    itranslation=ckanext.itranslation.plugin:ExampleITranslationPlugin
    [babel.extractors]
    ckan = ckan.lib.extract:extract_ckan
    
    message_extractors={
        'ckanext': [
            ('**.py', 'python', None),
            ('**.js', 'javascript', None),
            ('**/templates/**.html', 'ckan', None),
        ],
    }
)
```

These lines will already be present in our example, but if you are adding internationalization to an older extension, you may need to add them. If you have your templates in a directory differing from the default location (`ckanext/yourplugin/i18n`), you may need to change the `message_extractors` stanza. You can read more about message extractors in the `babel` documentation.

**5.10. Internationalizing strings in extensions**
Add a directory to store your translations:

```bash
mkdir ckanext-itranslations/ckanext/itranslations/i18n
```

Next you will need a babel config file. Add a `setup.cfg` file containing the following (make sure you replace `itranslations` with the name of your extension):

```ini
[extract_messages]
keywords = translate isPlural
add_comments = TRANSLATORS:
output_file = ckanext/itranslation/i18n/ckanext-itranslation.pot
width = 80

[init_catalog]
domain = ckanext-itranslation
input_file = ckanext/itranslation/i18n/ckanext-itranslation.pot
output_dir = ckanext/itranslation/i18n

[update_catalog]
domain = ckanext-itranslation
input_file = ckanext/itranslation/i18n/ckanext-itranslation.pot
output_dir = ckanext/itranslation/i18n

[compile_catalog]
domain = ckanext-itranslation
directory = ckanext/itranslation/i18n
statistics = true
```

This file tells babel where the translation files are stored. You can then run the `extract_messages` command to extract the strings from your extension:

```bash
python setup.py extract_messages
```

This will create a template PO file named `ckanext/itranslations/i18n/ckanext-itranslation.pot`.

At this point, you can either upload and manage your translations using Transifex or manually edit your translations.

### 5.10.2 Manually create translations

We will create translation files for the `fr` locale. Create the translation PO files for the locale that you are translating for by running `init_catalog`:

```bash
python setup.py init_catalog -l fr
```

This will generate a file called `i18n/fr/LC_MESSAGES/ckanext-itranslation.po`. This file should contain the untranslated string on our template. You can manually add a translation for it by editing the `msgstr` section:

```plaintext
msgid "This is an untranslated string"
msgstr "This is a itranslated string"
```

### 5.10.3 Translations with Transifex

Once you have created your translations, you can manage them using Transifex. This is out side of the scope of this tutorial, but the Transifex documentation provides tutorials on how to upload translations and how to manage them.
using the command line client.

5.10.4 Compiling the catalog

Once the translation files (.po) have been updated, either manually or via Transifex, compile them by running:

```
python setup.py compile_catalog
```

This will generate a .mo file containing your translations that can be used by CKAN.

5.10.5 The ITranslation interface

Once you have created the translated strings, you will need to inform CKAN that your extension is translated by implementing the ITranslation interface in your extension. Edit your plugin.py to contain the following.

```python
# encoding: utf-8
from ckan import plugins
from ckan.plugins import toolkit
from ckan.lib.plugins import DefaultTranslation

class ExampleITranslationPlugin(plugins.SingletonPlugin, DefaultTranslation):
    plugins.implements(plugins.ITranslation)
    plugins.implements(plugins.IConfigurer)
    def update_config(self, config):
        toolkit.add_template_directory(config, 'templates')
```

You’re done! To test your translated extension, make sure you add the extension to your /etc/ckan/default/development.ini, run a `paster serve` command and browse to http://localhost:5000. You should find that switching to the fr locale in the web interface will change the home page string to this is an itranslated string.

Advanced ITranslation usage

If you are translating a CKAN extension that already exists, or you have structured your extension differently from the default layout. You may have to tell CKAN where to locate your translated files, you can do this by not having your plugin inherit from the DefaultTranslation class and instead implement the ITranslation interface yourself.

```
@i18n_directory()
Change the directory of the .
i18n_locales()
Change the list of locales that this plugin handles
i18n_domain()
Change the gettext domain handled by this plugin
```

5.11 Migration from Pylons to Flask

On CKAN 2.6, work started to migrate from the Pylons web framework to a more modern alternative, Flask. This will be a gradual process spanning multiple CKAN versions, where both the Pylons app and the Flask app will live side by side with their own controllers or blueprints which handle the incoming requests. The idea is that any other lower level code, like templates, logic actions and authorization are shared between them as much as possible. You can learn
more about the approach followed and the work already done on this page in the CKAN wiki:
https://github.com/ckan/ckan/wiki/Migration-from-Pylons-to-Flask

This page lists changes and deprecations that both core and extensions developers should be aware of going forward, as well as common exceptions and how to fix them.

5.11.1 Always import methods and objects from the plugins toolkit if available

This is a good practice in general when writing extensions but in the context of the Flask migration it becomes specially important with these methods and objects:

```python
from ckan.plugins.toolkit import url_for, redirect_to, request, config

url_for()
redirect_to()
request
config
```

The reason is that these are actually wrappers provided by CKAN that will proxy the call to the relevant Pylons or Flask underlying object or method depending on who is handling the request. For instance in the `config` case, if you use `pylons.config` directly from your extension changes in configuration will only be applied to the Pylons application, and the Flask application will be misconfigured.

**Note:** `config` was added to the plugins toolkit on CKAN 2.6. If your extension needs to target CKAN versions lower and greater than CKAN 2.6 you can use `ckantoolkit <https://github.com/ckan/ckantoolkit>`, a separate package that provides wrappers for cross-version CKAN compatibility:

```python
from ckantoolkit import config
```
CHAPTER 6

Theming guide

Changed in version 2.0: The CKAN frontend was completely rewritten for CKAN 2.0, so most of the tutorials below don’t apply to earlier versions of CKAN.

The following sections will teach you how to customize the content and appearance of CKAN pages by developing your own CKAN themes.

See also:

Getting started  If you just want to do some simple customizations such as changing the title of your CKAN site, or making some small CSS customizations, Getting started documents some simple configuration settings you can use.

Note:  Before you can start developing a CKAN theme, you’ll need a working source install of CKAN on your system. If you don’t have a CKAN source install already, follow the instructions in Installing CKAN from source before continuing.

Note:  CKAN theme development is a technical topic, for web developers. The tutorials below assume basic knowledge of:

- The Python programming language
- HTML
- CSS
- JavaScript

We also recommend familiarizing yourself with:

- Jinja2 templates
- Bootstrap
- jQuery
Note: Starting from CKAN version 2.8 the Bootstrap version used in the default CKAN theme is Bootstrap 3. For backwards compatibility, Bootstrap 2 templates will be included in CKAN core for a few versions, but they will be eventually removed so you are encouraged to update your custom theme to use Bootstrap 3. You can select which set of templates to use (Bootstrap 3 or 2) by using the `ckan.base_public_folder` and `ckan.base_templates_folder` configuration options.

6.1 Customizing CKAN’s templates

CKAN pages are generated from Jinja2 template files. This tutorial will walk you through the process of writing your own template files to modify and replace the default ones, and change the layout and content of CKAN pages.

See also:

* **String internationalization** How to mark strings for translation in your template files.

6.1.1 Creating a CKAN extension

A CKAN theme is simply a CKAN plugin that contains some custom templates and static files, so before getting started on our CKAN theme we’ll have to create an extension and plugin. For a detailed explanation of the steps below, see [Writing extensions tutorial](#).

1. Use the `paster create` command to create an empty extension:
   ```bash
   . /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src
   paster --plugin=ckan create -t ckanext ckanext-example_theme
   ```

2. Create the file `ckanext-example_theme/ckanext/example_theme/plugin.py` with the following contents:
   ```python
   # encoding: utf-8

   import ckan.plugins as plugins

   class ExampleThemePlugin(plugins.SingletonPlugin):
       '''An example theme plugin.'''
       pass
   ```

3. Edit the `entry_points` in `ckanext-example_theme/setup.py` to look like this:
   ```python
   entry_points='''
   [ckan.plugins]
   example_theme=ckanext.example_theme.plugin:ExampleThemePlugin
   '',
   ```

4. Run `python setup.py develop`:
   ```bash
   cd ckanext-example_theme
   python setup.py develop
   ```
5. Add the plugin to the `ckan.plugins` setting in your `/etc/ckan/default/development.ini` file:

```
ckan.plugins = stats text_view recline_view example_theme
```

6. Start CKAN in the development web server:

```
$ paster serve --reload /etc/ckan/default/development.ini
```

Starting server in PID 13961.

serving on 0.0.0.0:5000 view at http://127.0.0.1:5000

Open the CKAN front page in your web browser. If your plugin is in the `ckan.plugins` setting and CKAN starts without crashing, then your plugin is installed and CKAN can find it. Of course, your plugin doesn’t do anything yet.

### 6.1.2 Replacing a default template file

Every CKAN page is generated by rendering a particular template. For each page of a CKAN site there’s a corresponding template file. For example the front page is generated from the `ckan/templates/home/index.html` file, the `/about` page is generated from `ckan/templates/home/about.html`, the datasets page at `/dataset` is generated from `ckan/templates/package/search.html`, etc.

To customize pages, our plugin needs to register its own custom template directory containing template files that override the default ones. Edit the `ckanext-example_theme/ckanext/example_theme/plugin.py` file that we created earlier, so that it looks like this:

```python
# encoding: utf-8

'''plugin.py

...
import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit

class ExampleThemePlugin(plugins.SingletonPlugin):
    '''An example theme plugin.''
    ...
    # Declare that this class implements IConfigurer.
    plugins.implements(plugins.IConfigurer)
    def update_config(self, config):
        # Add this plugin's templates dir to CKAN's extra_template_paths, so
        # that CKAN will use this plugin's custom templates.
        # 'templates' is the path to the templates dir, relative to this
        # plugin.py file.
        toolkit.add_template_directory(config, 'templates')

This new code does a few things:

1. It imports CKAN’s `plugins` module:

```python
import ckan.plugins.toolkit as toolkit
```

6.1. Customizing CKAN's templates
The plugins toolkit is a Python module containing core functions, classes and exceptions for CKAN plugins to use. For more about the plugins toolkit, see Writing extensions tutorial.

2. It calls `implements()` to declare that it implements the `IConfigurer` plugin interface:

```python
plugins.implements(plugins.IConfigurer)
```

This tells CKAN that our `ExampleThemePlugin` class implements the methods declared in the `IConfigurer` interface. CKAN will call these methods of our plugin class at the appropriate times.

3. It implements the `update_config()` method, which is the only method declared in the `IConfigurer` interface:

```python
def update_config(self, config):
    
    # Add this plugin's templates dir to CKAN's extra_template_paths, so
    # that CKAN will use this plugin's custom templates.
    # 'templates' is the path to the templates dir, relative to this
    # plugin.py file.
    toolkit.add_template_directory(config, 'templates')
```

CKAN will call this method when it starts up, to give our plugin a chance to modify CKAN's configuration settings. Our `update_config()` method calls `add_template_directory()` to register its custom template directory with CKAN. This tells CKAN to look for template files in `ckanext-example_theme/ckanext/example_theme/templates` whenever it renders a page. Any template file in this directory that has the same name as one of CKAN's default template files, will be used instead of the default file.

Now, let's customize the CKAN front page. We first need to discover which template file CKAN uses to render the front page, so we can replace it. Set `debug` to `true` in your `/etc/ckan/default/development.ini` file:

```
[DEFAULT]

# WARNING: *THIS SETTING MUST BE SET TO FALSE ON A PRODUCTION ENVIRONMENT*
default = true
```

Reload the CKAN front page in your browser, and you should see a Debug link in the footer at the bottom of the page. Click on this link to open the debug footer. The debug footer displays various information useful for CKAN frontend development and debugging, including the names of the template files that were used to render the current page:
The first template file listed is the one we’re interested in:

```
Template name: home/index.html
Template path: /usr/lib/ckan/default/src/ckan/ckan/templates/home/index.html
```

This tells us that `home/index.html` is the root template file used to render the front page. The debug footer appears at the bottom of every CKAN page, and can always be used to find the page’s template files, and other information about the page.

**Note:** Most CKAN pages are rendered from multiple template files. The first file listed in the debug footer is the root template file of the page. All other template files used to render the page (listed further down in the debug footer) are either included by the root file, or included by another file that is included by the root file.

To figure out which template file renders a particular part of the page you have to inspect the source code of the template files, starting with the root file.

Now let’s override `home/index.html` using our plugins’ custom templates directory. Create the `ckanext-example_theme/ckanext/example_theme/templates` directory, create a home directory inside the templates directory, and create an empty `index.html` file inside the home directory:

```
ckanext-example_theme/
    ckanext/
        example_theme/
            templates/
                home/
                    index.html  <-- An empty file.
```
If you now restart the development web server (kill the server using Ctrl-c, then run the `paster serve` command again) and reload the CKAN front page in your web browser, you should see an empty page, because we’ve replaced the template file for the front page with an empty file.

**Note:** If you run `paster serve` with the `--reload` option, then it isn’t usually necessary to restart the server after editing a Python file, a template file, your CKAN config file, or any other CKAN file. If you’ve added a new file or directory, however, you need to restart the server manually.

### 6.1.3 Jinja2

CKAN template files are written in the Jinja2 templating language. Jinja template files, such as our `index.html` file, are simply text files that, when processed, generate any text-based output format such as HTML, XML, CSV, etc. Most of the template files in CKAN generate HTML.

We’ll introduce some Jinja2 basics below. Jinja2 templates have many more features than these, for full details see the Jinja2 docs.

**Expressions and variables**

Jinja2 *expressions* are snippets of code between `{{ ... }}` delimiters, when a template is rendered any expressions are evaluated and replaced with the resulting value.

The simplest use of an expression is to display the value of a variable, for example `{{ foo }}` in a template file will be replaced with the value of the variable `foo` when the template is rendered.

CKAN makes a number of global variables available to all templates. One such variable is `app_globals`, which can be used to access certain global attributes including some of the settings from your CKAN config file. For example, to display the value of the `ckan.site_title` setting from your config file you would put this code in any template file:

```html
<p>The title of this site is: {{ app_globals.site_title }}.</p>
```

**Note:** The `app_globals` variable is also sometimes called `g` (an alias), you may see `g` in some CKAN templates. See [Variables and functions available to templates](#).

**Note:** Not all config settings are available to templates via `app_globals`. The `sqlalchemy.url` setting, for example, contains your database password, so making that variable available to templates might be a security risk.

If you’ve added your own custom options to your config file, these will not be available in `app_globals` automatically. See [Accessing custom config settings from templates](#).

**Note:** If a template tries to render a variable or attribute that doesn’t exist, rather than crashing or giving an error message, the Jinja2 expression simply evaluates to nothing (an empty string). For example, these Jinja2 expressions will output nothing:

```html
{{ app_globals.an_attribute_that_does_not_exist }}

{{ a_variable_that_does_not_exist }}
```
If, on the other hand, you try to render an attribute of a variable that doesn’t exist, then Jinja2 will crash. For example, this Jinja2 expression will crash with an `UndefinedError: 'a_variable_that_does_not_exist' is undefined`:

```jinja
{{ a_variable_that_does_not_exist.an_attribute_that_does_not_exist }}
```

See the Jinja2 variables docs for details.

**Note:** Jinja2 expressions can do much more than print out the values of variables, for example they can call Jinja2’s global functions, CKAN’s template helper functions and any custom template helper functions provided by your extension, and use any of the literals and operators that Jinja provides.

See Variables and functions available to templates for a list of variables and functions available to templates.

### Tags

`ckan.site_title` is an example of a simple string variable. Some variables, such as `ckan.plugins`, are lists, and can be looped over using Jinja’s `{% for %}` tag.

Jinja tags are snippets of code between `{% ... %}` delimiters that control the logic of the template. For example, we can output a list of the currently enabled plugins with this code in any template file:

```html
<p>The currently enabled plugins are:</p>
<ul>
  {% for plugin in app_globals.plugins %}
  <li>{{ plugin }}</li>
  {% endfor %}
</ul>
```

Other variables, such as `ckan.tracking_enabled`, are booleans, and can be tested using Jinja’s `{% if %}` tag:

```jinja
{% if g.tracking_enabled %}
<p>CKAN's page-view tracking feature is enabled.</p>
{% else %}
<p>CKAN's page-view tracking feature is <i>not</i> enabled.</p>
{% endif %}
```

### Comments

Finally, any text between `{# ... #}` delimiters in a Jinja2 template is a comment, and will not be output when the template is rendered:

`#{ This text will not appear in the output when this template is rendered. #}`

### 6.1.4 Extending templates with `{% ckan_extends %}`

CKAN provides a custom Jinja tag `{% ckan_extends %}` that we can use to declare that our `home/index.html` template extends the default `home/index.html` template, instead of completely replacing it. Edit the empty `index.html` file you just created, and add one line:
If you now reload the CKAN front page in your browser, you should see the normal front page appear again. When
CKAN processes our `index.html` file, the `{% ckan_extends %}` tag tells it to process the default home/
index.html file first.

### 6.1.5 Replacing template blocks with `{% block %}`

Jinja templates can contain *blocks* that child templates can override. For example, CKAN’s default `home/layout1.
html` template (one of the files used to render the CKAN front page) has a block that contains the Jinja and HTML
code for the “featured group” that appears on the front page:

```latex
{% block featured_group %}
    {%% snippet 'home/snippets/featured_group.html' %}
    {%% endblock %}
```

*Note:* This code calls a *template snippet* that contains the actual Jinja and HTML code for the featured group, more
on snippets later.

*Note:* The CKAN front page supports a number of different layouts: layout1, layout2, layout3, etc. The layout can be
chosen by a sysadmin using the *admin page*. This tutorial assumes your CKAN is set to use the first (default) layout.

When a custom template file extends one of CKAN’s default template files using `{% ckan_extends %}`, it can
replace any of the blocks from the default template with its own code by using `{% block %}`. Create the file
ckanext-example_theme/ckanext/example_theme/templates/home/layout1.html with these
contents:

```latex
{% ckan_extends %}

{% block featured_group %}
    Hello block world!
{% endblock %}
```

This file extends the default `layout1.html` template, and overrides the `featured_group` block. Restart the
development web server and reload the CKAN front page in your browser. You should see that the featured groups
section of the page has been replaced, but the rest of the page remains intact.

*Note:* Most template files in CKAN contain multiple blocks. To find out what blocks a template has, and which block
renders a particular part of the page, you have to look at the source code of the default template files.

### 6.1.6 Extending parent blocks with Jinja’s `{% super() %}`

If you want to add some code to a block but don’t want to replace the entire block, you can use Jinja’s `{% super() %}` tag:

```latex
{% ckan_extends %}

{% block featured_group %}
```

(continues on next page)
When the child block above is rendered, Jinja will replace the `{{ super() }}` tag with the contents of the parent block. The `{{ super() }}` tag can be placed anywhere in the block.

### 6.1.7 Template helper functions

Now let’s put some interesting content into our custom template block. One way for templates to get content out of CKAN is by calling CKAN’s template helper functions.

For example, let’s replace the featured group on the front page with an activity stream of the site’s recently created, updated and deleted datasets. Change the code in `ckanext-example_theme/ckanext/example_theme/templates/home/layout1.html` to this:

```html
{% ckan_extends %}
{% block featured_group %}
{{ h.recently_changed_packages_activity_stream(limit=4) }}
{% endblock %}
```

Reload the CKAN front page in your browser and you should see a new activity stream:
To call a template helper function we use a Jinja2 expression (code wrapped in {{ ... }} brackets), and we use the global variable \texttt{h} (available to all templates) to access the helper:

\begin{verbatim}
{{ h.recently_changed_packages_activity_stream(limit=4) }}
\end{verbatim}

To see what other template helper functions are available, look at the template helper functions reference docs.

6.1.8 Adding your own template helper functions

Plugins can add their own template helper functions by implementing CKAN’s \texttt{ITemplateHelpers} plugin interface. (see Writing extensions tutorial for a detailed explanation of CKAN plugins and plugin interfaces).

Let’s add another item to our custom front page: a list of the most “popular” groups on the site (the groups with the most datasets). We’ll add a custom template helper function to select the groups to be shown. First, in our \texttt{plugin.py} file we need to implement \texttt{ITemplateHelpers} and provide our helper function. Change the contents of \texttt{plugin.py} to look like this:

```python
# encoding: utf-8

import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit

def most_popular_groups():
    """Return a sorted list of the groups with the most datasets.""
    # Get a list of all the site's groups from CKAN, sorted by number of
    # datasets.
    groups = toolkit.get_action('group_list')({
        'data_dict':
            'sort': 'package_count desc', 'all_fields': True
    })
    # Truncate the list to the 10 most popular groups only.
    groups = groups[:10]
    return groups

class ExampleThemePlugin(plugins.SingletonPlugin):
    """An example theme plugin."
    """
    plugins.implements(plugins.IConfigurer)
    # Declare that this plugin will implement ITemplateHelpers.
    plugins.implements(plugins.ITemplateHelpers)

    def update_config(self, config):
        # Add this plugin's templates dir to CKAN's extra_template_paths, so
        # that CKAN will use this plugin's custom templates.
        toolkit.add_template_directory(config, 'templates')

    def get_helpers(self):
        """Register the most_popular_groups() function above as a template
        helper function."

        # (continues on next page)
```

(continues on next page)
We’ve added a number of new features to plugin.py. First, we defined a function to get the most popular groups from CKAN:

```python
def most_popular_groups():
    '''Return a sorted list of the groups with the most datasets.''
    
    # Get a list of all the site's groups from CKAN, sorted by number of
    # datasets.
    groups = toolkit.get_action('group_list')(
        data_dict={'sort': 'package_count desc', 'all_fields': True})
    
    # Truncate the list to the 10 most popular groups only.
    groups = groups[:10]
    
    return groups
```

This function calls one of CKAN’s action functions to get the groups from CKAN. See Writing extensions tutorial for more about action functions.

Next, we called `implements()` to declare that our class now implements `ITemplateHelpers`:

```python
plugins.implements(plugins.ITemplateHelpers)
```

Finally, we implemented the `get_helpers()` method from `ITemplateHelpers` to register our function as a template helper:

```python
def get_helpers(self):
    '''Register the most_popular_groups() function above as a template
    helper function.
    '''
    
    # Template helper function names should begin with the name of the
    # extension they belong to, to avoid clashing with functions from
    # other extensions.
    return {'example_theme_most_popular_groups': most_popular_groups}
```

Now that we’ve registered our helper function, we need to call it from our template. As with CKAN’s default template helpers, templates access custom helpers via the global variable `h`. Edit `ckanext-example_theme/ckanext/example_theme/templates/home/layout1.html` to look like this:

```html
{% ckan extends %}
{% block featured_group %}
  {{ h.recently_changed_packages_activity_stream(limit=4) }}
{% endblock %}
{% block featured_organization %}

  {% # Show a list of the site's most popular groups. # %}
  <h3>Most popular groups</h3>

{% endblock %}

(continues on next page)
```

---

## 6.1. Customizing CKAN’s templates

(continues from previous page)

```python
# Template helper function names should begin with the name of the
# extension they belong to, to avoid clashing with functions from
# other extensions.
return {'example_theme_most_popular_groups': most_popular_groups}
```
Now reload your CKAN front page in your browser. You should see the featured organization section replaced with a list of the most popular groups:

![Most popular groups](image)

Simply displaying a list of group titles isn’t very good. We want the groups to be hyperlinked to their pages, and also to show some other information about the group such as its description and logo image. To display our groups nicely, we’ll use CKAN’s template snippets…

### 6.1.9 Template snippets

**Template snippets** are small snippets of template code that, just like helper functions, can be called from any template file. To call a snippet, you use another of CKAN’s custom Jinja2 tags: `{% snippet %}`. CKAN comes with a selection of snippets, which you can find in the various `snippets` directories in `ckan/templates/`, such as `ckan/templates/snippets/` and `ckan/templates/package/snippets/`. For a complete list of the default snippets available to templates, see [Template snippets reference](#).

`ckan/templates/group/snippets/group_list.html` is a snippet that renders a list of groups nicely (it’s used to render the groups on CKAN’s `/group` page and on user dashboard pages, for example):

```html
{%#
Display a grid of group items.

groups - A list of groups.

Example:

{% snippet "group/snippets/group_list.html" %}
#
{% block group_list %}
<ul class="media-grid" data-module="media-grid">
{% block group_list_inner %}
{% for group in groups %}
{% snippet "group/snippets/group_item.html", group=group, position=loop.index %}
{% endfor %}
{% endblock %}
{% endblock %}
```
(As you can see, this snippet calls another snippet, group_item.html, to render each individual group.)

Let’s change our ckanext-example_theme/ckanext/example_theme/templates/home/layout1.html file to call this snippet:

```latex
{% ckan_extends %}
{% block featured_group %}

{{ h.recently_changed_packages_activity_stream(limit=4) }}

{% endblock %}

{% block featured_organization %}

<h3>Most popular groups</h3>

{% snippet 'group/snippets/group_list.html', groups=h.example_theme_most_popular_groups() %}

{% endblock %}

Here we pass two arguments to the {% snippet %} tag:

```latex
{% snippet 'group/snippets/group_list.html',
  groups=h.example_theme_most_popular_groups() %}

the first argument is the name of the snippet file to call. The second argument, separated by a comma, is the list of groups to pass into the snippet. After the filename you can pass any number of variables into a snippet, and these will all be available to the snippet code as top-level global variables. As in the group_list.html docstring above, each snippet’s docstring should document the parameters it requires.

If you reload your CKAN front page in your web browser now, you should see the most popular groups rendered in the same style as the list of groups on the /groups page:
This style isn’t really what we want for our front page, each group is too big. To render the groups in a custom style, we can define a custom snippet...

### 6.1.10 Adding your own template snippets

Just as plugins can add their own template helper functions, they can also add their own snippets. To add template snippets, all a plugin needs to do is add a `snippets` directory in its templates directory, and start adding files. The snippets will be callable from other templates immediately.

**Note:** For CKAN to find your plugins’ snippets directories, you should already have added your plugin’s custom template directory to CKAN, see Replacing a default template file.

Let’s create a custom snippet to display our most popular groups, we’ll put the `<h3>Most popular groups</h3>` heading into the snippet and make it nice and modular, so that we can reuse the whole thing on different parts of the site if we want to.

Create a new directory `ckanext-example_theme/ckanext/example_theme/templates/snippets` containing a file named `example_theme_most_popular_groups.html` with these contents:

```html
{# Renders a list of the site's most popular groups. #}

groups - the list of groups to render

(continues on next page)
# Most popular groups

```python
{% for group in groups %}
  <li>
    <a href="{{ h.url_for('group_read', action='read', id=group.name) }}">
      <h3>{{ group.display_name }}
      </a>
    </li>
  </ul>

Note: As in the example above, a snippet should have a docstring at the top of the file that briefly documents what the snippet does and what parameters it requires. See Snippets should have docstrings.

This code uses a Jinja2 for loop to render each of the groups, and calls a number of CKAN’s template helper functions:

- To hyperlink each group’s name to the group’s page, it calls `url_for()`.
- If the group has a description, it calls `markdown_extract()` to render the description nicely.
- If the group doesn’t have a description, it uses the `__()` function to mark the 'This group has no description' message for translation. When the page is rendered in a user’s web browser, this string will be shown in the user’s language (if there’s a translation of the string into that language).
- When rendering the group’s number of datasets, it uses the `ungettext()` function to mark the message for translation with localized handling of plural forms.

The code also accesses the attributes of each group: `{{ group.name }}, `{{ group.display_name }```, `{{ group.description }```, `{{ group.package_count }```, etc. To see what attributes a group or any other CKAN object (packages/datasets, organizations, users...) has, you can use CKAN’s API to inspect the object. For example to find out what attributes a group has, call the `group_show()` function.

Now edit your ckanext-example_theme/ckanext/example_theme/templates/home/layout1.html file and change it to use our new snippet instead of the default one:

```python
{% ckan_extends %}

{% block featured_group %}
  {{ h.recently_changed_packages_activity_stream(limit=4) }}
{% endblock %}

(continues on next page)
Restart the development web server and reload the CKAN front page and you should see the most popular groups rendered differently:

```
{% block featured_organization %}
  {% snippet 'snippets/example_theme_most_popular_groups.html',
               groups=h.example_theme_most_popular_groups() %}
{% endblock %}
```

Most popular groups

- Data Explorer Examples
  This group contains various real datasets that show CKAN’s data previewer in...
  6 Datasets
- Geospatial Data Explorer examples
  CKAN can plot both latitude and longitude as well as GeoJSON on a map. For...
  3 Datasets

**Warning:** Default snippets can be overridden. If a plugin adds a snippet with the same name as one of CKAN’s default snippets, the plugin’s snippet will override the default snippet wherever the default snippet is used.

Also if two plugins both have snippets with the same name, one of the snippets will override the other.

To avoid unintended conflicts, we recommend that snippet filenames begin with the name of the extension they belong to, e.g. snippets/example_theme_*.html. See **Avoid name clashes**.

**Note:** Snippets don’t have access to the global template context variable, c (see Variables and functions available to templates). Snippets can access other global variables such as h, app_globals and request, as well as any variables explicitly passed into the snippet by the parent template when it calls the snippet with a {% snippet %} tag.
6.1.11 HTML tags and CSS classes

Our additions to the front page so far don’t look very good or fit in very well with the CKAN theme. Let’s make them look better by tweaking our template to use the right HTML tags and CSS classes.

There are two places to look for CSS classes available in CKAN:

1. The Bootstrap 2.3.2 docs. All of the HTML, CSS and JavaScript provided by Bootstrap is available to use in CKAN.

2. CKAN’s development primer page, which can be found on any CKAN site at /testing/primer, for example demo.ckan.org/testing/primer.

The primer page demonstrates many of the HTML and CSS elements available in CKAN, and by viewing the source of the page you can see what HTML tags and CSS classes they use.

Edit your example_theme_most_popular_groups.html file to look like this:

```
{% # Renders a list of the site’s most popular groups. %} 

<div class="box">
  <header class="module-heading">
    <h3>Most popular groups</h3>
  </header>
  <section class="module-content">
    <ul class="unstyled">
      {% for group in h.example_theme_most_popular_groups() %}
        <li>
          <a href="{{ h.url_for('group_read', action='read', id=group.name) }}">
            <h3>{{ group.display_name }}</h3>
          </a>
          <p>{{ h.markdown_extract(group.description, extract_length=80) }}</p>
        </li>
      {% endfor %}
    </ul>
  </section>
</div>
```

This simply wraps the code in a <div class="box">, a <header class="module-heading">, and a <section class="module-content">. We also added Bootstrap’s class="unstyled" to the <ul> tag to get rid of the bullet points. If you reload the CKAN front page, the most popular groups should look much better.

To wrap your activity stream in a similar box, edit layout1.html to look like this:

```
{% ckan_extends %}
{% block featured_group %}
(continues on next page)
```
6.1.12 Accessing custom config settings from templates

Not all CKAN config settings are available to templates via `app_globals`. In particular, if an extension wants to use its own custom config setting, this setting will not be available. If you need to access a custom config setting from a template, you can do so by wrapping the config setting in a helper function.

See also:
For more on custom config settings, see Using custom config settings in extensions.

Todo: I’m not sure if making config settings available to templates like this is a very good idea. Is there an alternative best practice?

Let’s add a config setting, `show_most_popular_groups`, to enable or disable the most popular groups on the front page. First, add a new helper function to `plugin.py` to wrap the config setting.

```python
# encoding: utf-8

import ckan.plugins as plugins
import ckan.plugins.toolkit as toolkit
```
from ckan.common import config

def show_most_popular_groups():
    '''Return the value of the most_popular_groups config setting.
    To enable showing the most popular groups, add this line to the
    [app:main] section of your CKAN config file:
    
    ckan.example_theme.show_most_popular_groups = True
    
    Returns `False` by default, if the setting is not in the config file.
    :rtype: bool
    '''
    value = config.get('ckan.example_theme.show_most_popular_groups', False)
    value = toolkit.asbool(value)
    return value

def most_popular_groups():
    '''Return a sorted list of the groups with the most datasets.''
    
    # Get a list of all the site's groups from CKAN, sorted by number of
    # datasets.
    groups = toolkit.get_action('group_list')({
        'data_dict': {'sort': 'packages desc', 'all_fields': True})
    
    # Truncate the list to the 10 most popular groups only.
    groups = groups[:10]
    return groups

class ExampleThemePlugin(plugins.SingletonPlugin):
    '''An example theme plugin.
    '''

    plugins.implements(plugins.IConfigurer)
    plugins.implements(plugins.ITemplateHelpers)

    def update_config(self, config):
        # Add this plugin's templates dir to CKAN's extra_template_paths, so
        # that CKAN will use this plugin's custom templates.
        toolkit.add_template_directory(config, 'templates')

    def get_helpers(self):
        '''Register the most_popular_groups() function above as a template
        helper function.
        '''
        # Template helper function names should begin with the name of the
        # extension they belong to, to avoid clashing with functions from
# other extensions.
return {'example_theme_most_popular_groups': most_popular_groups,
'example_theme_show_most_popular_groups':
show_most_popular_groups,
}

def show_most_popular_groups():
    '''Return the value of the most_popular_groups config setting.

    To enable showing the most popular groups, add this line to the
    [app:main] section of your CKAN config file:

    ckan.example_theme.show_most_popular_groups = True

    Returns `False` by default, if the setting is not in the config file.

    :rtype: bool
    '''
    value = config.get('ckan.example_theme.show_most_popular_groups', False)
    value = toolkit.asbool(value)
    return value

Note: Names of config settings provided by extensions should include the name of the extension, to avoid conflicting
with core config settings or with config settings from other extensions. See Avoid name clashes.

Now we can call this helper function from our layout1.html template:

```html
{% block featured_organization %}
{% if h.example_theme_show_most_popular_groups() %}
{% snippet 'snippets/example_theme_most_popular_groups.html' %}
{% else %}
{{ super() }}
{% endif %}
{% endblock %}
```

If the user sets this config setting to `True` in their CKAN config file, then the most popular groups will be displayed
on the front page, otherwise the block will fall back to its default contents.

6.2 Adding static files

You may need to add some custom static files to your CKAN site and use them from your templates, for example
image files, PDF files, or any other static files that should be returned as-is by the webserver (as opposed to Jinja
template files, which CKAN renders before returning them to the user).

By adding a directory to CKAN’s `extra_public_paths` config setting, a plugin can make a directory of static files
available to be used or linked to by templates. Let’s add a static image file, and change the home page template to use
our file as the promoted image on the front page.

See also:

Adding CSS and JavaScript files using Fanstatic
If you’re adding CSS files consider using Fanstatic instead of extra_public_paths, to take advantage of extra features. See Adding CSS and JavaScript files using Fanstatic. If you’re adding JavaScript modules you have to use Fanstatic, see Customizing CKAN’s JavaScript.

First, create a public directory in your extension with a promoted-image.jpg file in it:

```
ckanext-example_theme/
  ckanext/
    example_theme/
      public/
        promoted-image.jpg
```

promoted-image.jpg should be a 420x220px JPEG image file. You could use this image file for example:

![Image Preview](promoted-image.jpg)

Then in plugin.py, register your public directory with CKAN by calling the add_public_directory() function. Add this line to the update_config() function:

```python
def update_config(self, config):
    # Add this plugin's templates dir to CKAN's extra_template_paths, so
    # that CKAN will use this plugin's custom templates.
    toolkit.add_template_directory(config, 'templates')

    # Add this plugin's public dir to CKAN's extra_public_paths, so
    # that CKAN will use this plugin's custom static files.
    toolkit.add_public_directory(config, 'public')
```

If you now browse to 127.0.0.1:5000/promoted-image.jpg, you should see your image file.

To replace the image on the front page with your custom image, we need to override the promoted.html template snippet. Create the following directory and file:

```
ckanext-example_theme/
  ckanext/
    example_theme/
      templates/
        home/
          snippets/
            promoted.html
```

Edit your new promoted.html snippet, and insert these contents:

```html
6.2. Adding static files 281
```
After calling {% ckan_extends %} to declare that it extends (rather than completely replaces) the default promoted.html snippet, this custom snippet overrides two of promoted.html's template blocks. The first block replaces the caption text of the promoted image. The second block replaces the <img> tag itself, pointing it at our custom static image file:

```template
{% block home_image_caption %}
{{ _("CKAN's data previewing tool has many powerful features") }}
{% endblock %}

{% block home_image_content %}
<a class="media-image" href="#">
  <img src="/promoted-image.jpg" alt="Featured image"
       width="420" height="220" />
</a>
{% endblock %}
```

If you now restart the development web server and reload the CKAN front page in your browser, you should see the promoted image replaced with our custom one:
6.3 Customizing CKAN’s CSS

See also:

There’s nothing special about CSS in CKAN, once you’ve got started with editing CSS in CKAN (by following the tutorial below), then you just use the usual tools and techniques to explore and hack the CSS. We recommend using your browser’s web development tools to explore and experiment with the CSS, then using any good text editor to edit your extension’s CSS files as needed. For example:

Firefox developer tools These include a Page Inspector and a Style Editor
Firebug Another web development toolkit for Firefox
Chrome developer tools Tools for inspecting and editing CSS in Google Chrome
Mozilla Developer Network’s CSS section A good collection of CSS documentation and tutorials

Extensions can add their own CSS files to modify or extend CKAN’s default CSS. Create an example_theme.css file in your extension’s public directory:

```
ckanext-example_theme/
   ckanext/
      example_theme/
```

(continues on next page)
Add this CSS into the `example_theme.css` file, to change the color of CKAN's “account masthead” (the bar across the top of the site that shows the logged-in user's account info):

```css
.account-masthead {
    background-color: rgb(40, 40, 40);
}
```

If you restart the development web server you should be able to open this file at http://127.0.0.1:5000/example_theme.css in a web browser.

To make CKAN use our custom CSS we need to override the `base.html` template, this is the base template which the templates for all CKAN pages extend, so if we include a CSS file in this base template then the file will be included in every page of your CKAN site. Create the file:

```bash
ckanext-example_theme/
   ckanext/
      example_theme/
         templates/
            base.html
```

and put this Jinja code in it:

```jinja
{% ckan_extends %}
{% block styles %}
{{ super() }}
<link rel="stylesheet" href="/example_theme.css" />
{% endblock %}
```

The default `base.html` template defines a `styles` block which can be extended to link to custom CSS files (any code in the styles block will appear in the `<head>` of the HTML page).

Restart the development web server and reload the CKAN page in your browser, and you should see the background color of the account masthead change:

This custom color should appear on all pages of your CKAN site.

Now that we have CKAN using our CSS file, we can add more CSS rules to the file and customize CKAN's CSS as much as we want. Let's add a bit more code to our `example_theme.css` file. This CSS implements a partial imitation of the `datahub.io` theme (circa 2013):
6.3. Customizing CKAN’s CSS
/* The user account info text and icons, when the user’s pointer is hovering over them. */
.account-masthead .account ul li a:hover {
  background-color: black;
}

/* The user account info text and icons, when the user’s pointer is hovering over them. */
.account-masthead .account ul li a:hover {
  background-color: rgba(255, 255, 255, 0.7);
  color: rgba(255, 255, 255, 0.6);
}

/* The main masthead bar that contains the site logo, nav links, and search */
.masthead {
  background-color: #3d3d3d;
}

/* The "navigation pills" in the masthead (the links to Datasets, Organizations, etc) when the user’s pointer hovers over them. */
.masthead .navigation .nav-pills li a:hover {
  background-color: rgb(48, 48, 48);
  color: white;
}

/* The "active" navigation pill (for example, when you’re on the /dataset page the "Datasets" link is active). */
.masthead .navigation .nav-pills li.active a {
  background-color: rgb(74, 74, 74);
}

/* The "box shadow" effect that appears around the search box when it has the keyboard cursor’s focus. */
.masthead input[type="text"]:focus {
  -webkit-box-shadow: inset 0px 0px 2px 0px rgba(0, 0, 0, 0.7);
  box-shadow: inset 0px 0px 2px 0px rgba(0, 0, 0, 0.7);
}

/* The content in the middle of the front page */
.box {
  box-shadow: none;
}

/* Remove the borders around the "Welcome to CKAN" and "Search Your Data" boxes. */
.hero .box {
  border: none;
}

/* Change the colors of the "Search Your Data" box. */
.homepage .module-search .module-content {
  color: rgb(68, 68, 68);
  background-color: white;
}

/* Change the background color of the "Popular Tags" box. */
.homepage .module-search .tags {
  background-color: rgb(61, 61, 61);
}
6.4 Adding CSS and JavaScript files using Fanstatic

If you’re adding CSS files to your theme, you can add them using Fanstatic rather than the simple extra_public_paths method described in Adding static files. If you’re adding a JavaScript module, you must use Fanstatic.

Using Fanstatic to add JavaScript and CSS files takes advantage of Fanstatic’s features, such as automatically serving minified files in production, caching and bundling files together to reduce page load times, specifying dependencies between files so that the files a page needs (and only the files it needs) are always loaded, and other tricks to optimize page load times.

Note: CKAN will only serve *.js and *.css files as Fanstatic resources, other types of static files (eg. image files, PDF files) must be added using the extra_public_paths method described in Adding static files.

Adding a custom JavaScript or CSS file to CKAN using Fanstatic is simple. We’ll demonstrate by changing our previous custom CSS example (see Customizing CKAN’s CSS) to serve the CSS file with Fanstatic.

1. First, create a fanstatic directory in your extension and move the CSS file from public into fanstatic:
2. Use CKAN's `add_resource()` function to register your fanstatic directory with CKAN. Edit the `update_config()` method in your `plugin.py` file:

```python
def update_config(self, config):
    # Add this plugin's templates dir to CKAN's extra_template_paths, so
    # that CKAN will use this plugin's custom templates.
    toolkit.add_template_directory(config, 'templates')

    # Add this plugin's public dir to CKAN's extra_public_paths, so
    # that CKAN will use this plugin's custom static files.
    toolkit.add_public_directory(config, 'public')

    # Register this plugin's fanstatic directory with CKAN.
    # Here, 'fanstatic' is the path to the fanstatic directory
    # (relative to this plugin.py file), and 'example_theme' is the name
    # that we'll use to refer to this fanstatic directory from CKAN
    # templates.
    toolkit.add_resource('fanstatic', 'example_theme')
```

3. Finally, edit your extension’s `templates/base.html` file and use CKAN’s custom Jinja2 tag `{% resource %}` instead of the normal `<link>` tag to import the file:

```html
{% ckan_extends %}

{% block styles %}
{{ super() }}

{% resource 'example_theme/example_theme.css' %}
{% endblock %}
```

**Note:** You can put `{% resource %}` tags anywhere in any template, and Fanstatic will insert the necessary `<style>` and `<script>` tags to include your CSS and JavaScript files and their dependencies in the right places in the HTML output (CSS files in the HTML `<head>`, JavaScript files at the bottom of the page).

Resources will not be included on the line where the `{% resource %}` tag is.

**Note:** A config file can be used to configure how Fanstatic should serve each resource file (whether or not to bundle files, what order to include files in, whether to include files at the top or bottom of the page, dependencies between files, etc.) See Resources for details.
6.5 Customizing CKAN’s JavaScript

JavaScript code in CKAN is broken down into modules: small, independent units of JavaScript code. CKAN themes can add JavaScript features by providing their own modules. This tutorial will explain the main concepts involved in CKAN JavaScript modules and walk you through the process of adding custom modules to themes.

See also:

This tutorial assumes a basic understanding of CKAN plugins and templating, see:

- Extending guide
- Customizing CKAN’s templates

See also:

This tutorial assumes a basic understanding of JavaScript and jQuery, see:

- JavaScript on the Mozilla Developer Network
- jQuery.com, including the jQuery Learning Center

String internationalization How to mark strings for translation in your JavaScript code.

6.5.1 Overview

The idea behind CKAN’s JavaScript modules is to keep the code simple and easy to test, debug and maintain, by breaking it down into small, independent modules. JavaScript modules in CKAN don’t share global variables, and don’t call each other’s code.

These JavaScript modules are attached to HTML elements in the page, and enhance the functionality of those elements. The idea is that an HTML element with a JavaScript module attached should still be fully functional even if JavaScript is completely disabled (e.g., because the user’s web browser doesn’t support JavaScript). The user experience may not be quite as nice without JavaScript, but the functionality should still be there. This is a programming technique known as graceful degradation, and is a basic tenet of web accessibility.

In the sections below, we’ll walk you through the steps to add a new JavaScript feature to CKAN - dataset info popovers. We’ll add an info button to each dataset on the datasets page which, when clicked, opens a popover containing some extra information and user actions related to the dataset:

![A Novel By Tolstoy](image)

A Novel By Tolstoy

Some test notes A 3rd level heading Some bo umlaut ü 66-style quote “ foreign word: thŭmb

plain text JSON

You can also access this registry using the API (see A...
6.5.2 Initializing a JavaScript module

To get CKAN to call some custom JavaScript code, we need to:

1. Implement a JavaScript module, and register it with CKAN. Create the file `ckanext-example_theme/ckanext/example_theme_docs/fanstatic/example_theme_popover.js`, with these contents:

```javascript
// Enable JavaScript's strict mode. Strict mode catches some common
// programming errors and throws exceptions, prevents some unsafe actions from
// being taken, and disables some confusing and bad JavaScript features.
"use strict";

ckan.module('example_theme_popover', function ($) {
    return {
        initialize: function () {
            console.log("I've been initialized for element: ", this.el);
        }
    };
});
```

This bit of JavaScript calls the `ckan.module()` function to register a new JavaScript module with CKAN. `ckan.module()` takes two arguments: the name of the module being registered (`'example_theme_popover'` in this example) and a function that returns the module itself. The function takes two arguments, which we’ll look at later. The module is just a JavaScript object with a single attribute, `initialize`, whose value is a function that CKAN will call to initialize the module. In this example, the `initialize` function just prints out a confirmation message - this JavaScript module doesn’t do anything interesting yet.

**Note:** JavaScript module names should begin with the name of the extension, to avoid conflicting with other modules. See [Avoid name clashes](#).

**Note:** Each JavaScript module’s `initialize()` function is called on DOM ready.

2. Include the JavaScript module in a page, using Fanstatic, and apply it to one or more HTML elements on that page. We’ll override CKAN’s `package_item.html` template snippet to insert our module whenever a package is rendered as part of a list of packages (for example, on the dataset search page). Create the file `ckanext-example_theme/ckanext/example_theme_docs/templates/snippets/package_item.html` with these contents:

```html
{% ckan_extends %}
{% block content %}
{{ super() }}

#{ Use Fanstatic to include our custom JavaScript module. 
  A <script> tag for the module will be inserted in the right place at the 
  bottom of the page. #}
{% resource 'example_theme/example_theme_popover.js' %}

#{ Apply our JavaScript module to an HTML element. The data-module attribute, 
  which can be applied to any HTML element, tells CKAN to initialize an 
  instance of the named JavaScript module for the element. 
  The initialize() method of our module will be called with this HTML 

(continues on next page)
If you now restart the development server and open http://127.0.0.1:5000/dataset in your web browser, you should see an extra info button next to each dataset shown. If you open a JavaScript console in your browser, you should see the message that your module has printed out.

See also:
Most web browsers come with built-in developer tools including a JavaScript console that lets you see text printed by JavaScript code to `console.log()`, a JavaScript debugger, and more. For example:

- Firefox Developer Tools
- Firebug
- Chrome DevTools

If you have more than one dataset on your page, you’ll see the module’s message printed once for each dataset. The `package_item.html` template snippet is rendered once for each dataset that’s shown in the list, so your `<button>` element with the `data-module="example_theme_popover"` attribute is rendered once for each dataset, and CKAN creates a new instance of your JavaScript module for each of these `<button>` elements. If you view the source of your page, however, you’ll see that `example_theme_popover.js` is only included with a `<script>` tag once. Fanstatic is smart enough to deduplicate resources.

Note: JavaScript modules must be included as Fanstatic resources, you can’t add them to a public directory and include them using your own `<script>` tags.

6.5.3 this.options and this.el

Now let’s start to make our JavaScript module do something useful: show a Bootstrap popover with some extra info about the dataset when the user clicks on the info button.

First, we need our Jinja template to pass some of the dataset’s fields to our JavaScript module as `options`. Change `package_item.html` to look like this:

```html
<element as its this.el object. #>
<button data-module="example_theme_popover"
    class="btn"
    href="#">
    <i class="fa fa-info-circle"></i>
</button>
{% endblock %}

See also:
Using data-* attributes on the Mozilla Developer Network.

6.5. Customizing CKAN’s JavaScript
This adds some data-module-* attributes to our <button> element, e.g. data-module-title="{{ package.title }}" ({{ package.title }} is a Jinja2 expression that evaluates to the title of the dataset, CKAN passes the Jinja2 variable package to our template).

**Warning:** Although HTML 5 treats any attribute named data-* as a data attribute, only attributes named data-module-* will be passed as options to a CKAN JavaScript module. So we have to named our parameters data-module-title etc., not just data-title.

Now let’s make use of these options in our JavaScript module. Change example_theme_popover.js to look like this:

```javascript
"use strict";

/* example_theme_popover

This JavaScript module adds a Bootstrap popover with some extra info about a dataset to the HTML element that the module is applied to. Users can click on the HTML element to show the popover.

* title - the title of the dataset
* license - the title of the dataset’s copyright license
* num_resources - the number of resources that the dataset has.
*/

ckan.module('example_theme_popover', function ($) {
    return {
        initialize: function () {
            // Access some options passed to this JavaScript module by the calling template.
            var num_resources = this.options.num_resources;
            var license = this.options.license;

            // Format a simple string with the number of resources and the license, e.g. "3 resources, Open Data Commons Attribution License".
            var content = 'NUM resources, LICENSE'.replace('NUM', num_resources).replace('LICENSE', license);

            // Add a Bootstrap popover to the HTML element (this.el) that this JavaScript module was initialized on.
            this.el.popover({title: this.options.title, content: content, placement: 'left'});
        }
    };
});
```
Note: It’s best practice to add a docstring to the top of a JavaScript module, as in the example above, briefly documenting what the module does and what options it takes. See JavaScript modules should have docstrings.

Any data-module-* attributes on the HTML element are passed into the JavaScript module in the object this.options:

```
var num_resources = this.options.num_resources;
var license = this.options.license;
```

A JavaScript module can access the HTML element that it was applied to through the this.el variable. To add a popover to our info button, we call Bootstrap’s `popover()` function on the element, passing in an options object with some of the options that Bootstrap’s popovers accept:

```
// Add a Bootstrap popover to the HTML element (this.el) that this
// JavaScript module was initialized on.
this.el.popover({title: this.options.title,
    content: content,
    placement: 'left'});
```

See also:

For other objects and functions available to JavaScript modules, see Objects and methods available to JavaScript modules.

### 6.5.4 Default values for options

Default values for JavaScript module options can be provided by adding an options object to the module. If the HTML element doesn’t have a data-module-* attribute for an option, then the default will be used instead. For example...

Todo: Think of an example to do using default values.

### 6.5.5 Ajax, event handling and CKAN’s JavaScript sandbox

So far, we’ve used simple JavaScript string formatting to put together the contents of our popover. If we want the popover to contain much more complex HTML we really need to render a template for it, using the full power of Jinja2 templates and CKAN’s template helper functions. Let’s edit our plugin to use a Jinja2 template to render the contents of the popups nicely.

First, edit `package_item.html` to make it pass a few more parameters to the JavaScript module using data-module-* attributes:

```html
{% ckan_extends %}

{% block content %}{% super() %}

{% resource 'example_theme/example_theme_popover.js' %}
{% resource 'example_theme/example_theme_popover.css' %}

<button data-module="example_theme_popover"

(continues on next page)
We’ve also added a second {%- resource %} tag to the snippet above, to include a custom CSS file. We’ll see the contents of that CSS file later.

Next, we need to add a new template snippet to our extension that will be used to render the contents of the popovers. Create this example_theme_popover.html file:

```html
<%resource%

and put these contents in it:

```html
({# The contents for a dataset popover. #})

```html
<div class="context-info">
  <div class="nums">
    <dl>
      <dt>{{ _('Followers') }}</dt>
      <dd>{{ h.follow_count('dataset', id) }}</dd>
      <dt>{{ _('Resources') }}</dt>
      <dd>{{ num_resources }}</dd>
    </dl>
  </div>
  <div class="license">
    <dl>
      <dt>License</dt>
      <dd>{{ license_title }}</dd>
    </dl>
  </div>
  <div class="clearfix"></div>
  {{ h.follow_button('dataset', id) }}
  <a class="btn go-to-dataset" href="{{ h.url_for(controller='package', action='read', id=id) }}">
    <i class="fa fa-arrow-circle-right"></i>
  </a>
</div>
(continues on next page)
This is a Jinja2 template that renders some nice looking contents for a popover, containing a few bits of information about a dataset. It uses a number of CKAN’s Jinja2 templating features, including marking user-visible strings for translation and calling template helper functions. See Customizing CKAN’s templates for details about Jinja2 templating in CKAN.

Note: The new template file has to be in a templates/ajax_snippets/ directory so that we can use the template from our JavaScript code using CKAN’s getTemplate() function. Only templates from ajax_snippets directories are available from the getTemplate() function.

Next, edit fanstatic/example_theme_popover.js as shown below. There’s a lot going on in this new JavaScript code, including:

- Using Bootstrap’s popover API to show and hide popovers, and set their contents.
- Using jQuery’s event handling API to get our functions to be called when the user clicks on a button.
- Using a function from CKAN’s JavaScript sandbox.

The sandbox is a JavaScript object, available to all JavaScript modules as this.sandbox, that contains a collection of useful functions and variables.

this.sandbox.client is a CKAN API client written in JavaScript, that should be used whenever a JavaScript module needs to talk to the CKAN API, instead of modules doing their own HTTP requests.

this.sandbox.client.getTemplate() is a function that sends an asynchronous (ajax) HTTP request (i.e. send an HTTP request from JavaScript and receive the response in JavaScript, without causing the browser to reload the whole page) to CKAN asking for a template snippet to be rendered.

Hopefully the liberal commenting in the code below makes it clear enough what’s going on:

```javascript
"use strict";

ckan.module('example_theme_popover', function ($) {
  return {
    initialize: function () {

      // proxyAll() ensures that whenever an _on*() function from this
      // JavaScript module is called, the `this` variable in the function will
      // be this JavaScript module object.
      //
      // You probably want to call proxyAll() like this in the initialize()
      // function of most modules.
      //
      // This is a shortcut function provided by CKAN, it wraps jQuery's
      // proxy() function: http://api.jquery.com/jQuery.proxy/
      // $.proxyAll(this, /_on/);

      // Add a Bootstrap popover to the button. Since we don’t have the HTML
      // from the snippet yet, we just set the content to "Loading..."
      this.el.popover({title: this.options.title, html: true,
          content: this._('Loading...'), placement: 'left'});
    }
  }
});
```
// Add an event handler to the button, when the user clicks the button
// our _onClick() function will be called.
this.el.on('click', this._onClick);

// Whether or not the rendered snippet has already been received from CKAN.
_snippetReceived: false,

_onClick: function(event) {
    // Send an ajax request to CKAN to render the popover.html snippet.
    // We wrap this in an if statement because we only want to request
    // the snippet from CKAN once, not every time the button is clicked.
    if (!this._snippetReceived) {
        this.sandbox.client.getTemplate('example_theme_popover.html',
            this.options, 
            this._onReceiveSnippet);
        this._snippetReceived = true;
    }
},

// CKAN calls this function when it has rendered the snippet, and passes
// it the rendered HTML.
_onReceiveSnippet: function(html) {
    // Replace the popover with a new one that has the rendered HTML from the
    // snippet as its contents.
    this.el.popover('destroy');
    this.el.popover({title: this.options.title, html: true,
        content: html, placement: 'left'});
    this.el.popover('show');
},

});

Finally, we need some custom CSS to make the HTML from our new snippet look nice. In
package_item.html above we added a {% resource %} tag to include a custom CSS file. Now
we need to create that file, ckanext-example_theme/ckanext/example_theme/fanstatic/
example_theme_popover.css:

.dataset-list .popover .nums {
    /* We're reusing the .nums class from the dataset read page,
        * but we don't want the border, margin and padding, get rid of them. */
    border: none;
    margin: 0;
    padding: 0;

    /* We want the license and numbers to appear side by side, so float the
        * numbers list to the left and make it take up just over half of
        * the width of the popover. */
    float: left;
    width: 55%;
}
Restart CKAN, and your dataset popovers should be looking much better.

### 6.5.6 Error handling

What if our JavaScript makes an Ajax request to CKAN, such as our `getTemplate()` call above, and gets an error in response? We can simulate this by changing the name of the requested template file to one that doesn’t exist:

```javascript
this.sandbox.client.getTemplate('foobar.html',
   this.options,
   this._onReceiveSnippet);
```

If you reload the datasets page after making this change, you’ll see that when you click on a popover its contents remain `Loading...` If you have a development console open in your browser, you’ll see the error response from CKAN each time you click to open a popover.

Our JavaScript module’s `_onReceiveSnippet()` function is only called if the request gets a successful response from CKAN. `getTemplate()` also accepts a second callback function parameter that will be called when CKAN sends an error response. Add this parameter to the `getTemplate()` call:

```javascript
this.sandbox.client.getTemplate('foobar.html',
   this.options,
   this._onReceiveSnippet,
   this._onReceiveSnippetError);
```

Now add the new error function to the JavaScript module:

```javascript
_onReceiveSnippetError: function(error) {  
   this.el.popover('destroy');
   var content = error.status + ' ' + error.statusText + ' :(';
   this.el.popover({title: this.options.title, html: true,
                   content: content, placement: 'left'});
   this.el.popover('show');
   this._snippetReceived = true;
},
```

After making these changes, you should see that if CKAN responds with an error, the contents of the popover are replaced with the error message from CKAN.
6.5.7 Pubsub

You may have noticed that, with our example code so far, if you click on the info button of one dataset on the page then click on the info button of another dataset, both dataset’s popovers are shown. The first popover doesn’t disappear when the second appears, and the popovers may overlap. If you click on all the info buttons on the page, popovers for all of them will be shown at once:

To make one popover disappear when another appears, we can use CKAN’s `publish()` and `subscribe()` functions. These pair of functions allow different instances of a JavaScript module (or instances of different JavaScript modules) on the same page to talk to each other. The way it works is:

1. Modules can subscribe to events by calling `this.sandbox.client.subscribe()`, passing the ‘topic’ (a string that identifies the type of event to subscribe to) and a callback function.
2. Modules can call `this.sandbox.client.publish()` to publish an event for all subscribed modules to receive, passing the topic string and one or more further parameters that will be passed on as parameters to the receiver functions.
3. When a module calls `publish()`, any callback functions registered by previous calls to `subscribe()` with the same topic string will be called, and passed the parameters that were passed to publish.
4. If a module no longer wants to receive events for a topic, it calls `unsubscribe()`.

All modules that subscribe to events should have a `teardown()` function that unsubscribes from the event, to prevent memory leaks. CKAN calls the `teardown()` functions of modules when those modules are removed from the page. See `JavaScript modules should unsubscribe from events in teardown()`.
Warning: Don’t tightly couple your JavaScript modules by overusing pubsub. See Don’t overuse pubsub.

Remember that because we attach our `example_theme_popover.js` module to a `<button>` element that is rendered once for each dataset on the page, CKAN creates one instance of our module for each dataset. The only way these objects can communicate with each other so that one object can hide its popover when another object shows its popover, is by using pubsub.

Here’s a modified version of our `example_theme_popover.js` file that uses pubsub to make the dataset popovers disappear whenever a new popover appears:

```
"use strict";

ckan.module('example_theme_popover', function ($) {
    return {
        initialize: function () {
            $.proxyAll(this, /_on/);
            this.el.popover({title: this.options.title, html: true,
                content: this._('Loading...'), placement: 'left'});
            this.el.on('click', this._onClick);
            // Subscribe to 'dataset_popover_clicked' events.
            // Whenever any line of code publishes an event with this topic,
            // our _onPopoverClicked function will be called.
            this.sandbox.subscribe('dataset_popover_clicked',
                this._onPopoverClicked);
        },
        teardown: function () {
            this.sandbox.unsubscribe('dataset_popover_clicked',
                this._onPopoverClicked);
        },
        _snippetReceived: false,
        _onClick: function (event) {
            if (!this._snippetReceived) {
                this.sandbox.client.getTemplate('example_theme_popover.html',
                    this.options,
                    this._onReceiveSnippet);
                this._snippetReceived = true;
            }
            // Publish a 'dataset_popover_clicked' event for other interested
            // JavaScript modules to receive. Pass the button that was clicked as a
            // parameter to the receiver functions.
            this.sandbox.publish('dataset_popover_clicked', this.el);
        },
        _onPopoverClicked: function (button) {
            // Wrap this in an if, because we don’t want this object to respond to
            // its own 'dataset_popover_clicked' event.
            if (button != this.el) {
                // (continues on next page)
            }
        }
    }
});
```

6.5. Customizing CKAN’s JavaScript

299
// Hide this button's popover.  
// (If the popover is not currently shown anyway, this does nothing).  
this.el.popover('hide');
}
},
_onReceiveSnippet: function(html) {
  this.el.popover('destroy');
  this.el.popover({title: this.options.title, html: true,  
                    content: html, placement: 'left'});
  this.el.popover('show');
},
});

6.5.8 jQuery plugins

CKAN provides a number of custom jQuery plugins for JavaScript modules to use by default, see CKAN jQuery plugins reference. Extensions can also add their own jQuery plugins, and the plugins will then be available to all JavaScript code via the this.$ object.

See also:

How to Create a Basic Plugin jQuery’s own documentation on writing jQuery plugins. Read this for all the details on writing jQuery plugins, here we’ll only provide a simple example and show you how to integrate it with CKAN.

It’s a good idea to implement any JavaScript functionality not directly related to CKAN as a jQuery plugin. That way your CKAN JavaScript modules will be smaller as they’ll contain only the CKAN-specific code, and your jQuery plugins will also be reusable on non-CKAN sites. CKAN core uses jQuery plugins to implement features including date formatting, warning users about unsaved changes when leaving a page containing a form without submitting the form, restricting the set of characters that can be typed into an input field, etc.

Let’s add a jQuery plugin to our CKAN extension that makes our info buttons turn green when clicked.

Todo: Replace this with a more realistic example.

First we need to write the jQuery plugin itself. Create the file ckanext-example_theme/ckanext/example_theme/fanstatic/jquery.greenify.js with the following contents:

"use strict";

(function (jQuery) {
  jQuery.fn.greenify = function() {
    this.css( "color", "green" );
    return this;
  };
})(this.jQuery);

If this JavaScript code looks a little confusing at first, it’s probably because it’s using the Immediately-Invoked Function Expression (IIFE) pattern. This is a common JavaScript code pattern in which an anonymous function is created and then immediately called once, in a single expression. In the example above, we create an unnamed function that
takes a single parameter, \texttt{jQuery}, and then we call the function passing \texttt{this.jQuery} to its \texttt{jQuery} parameter. The code inside the body of the function is the important part. Writing jQuery plugins in this way ensures that any variables defined inside the plugin are private to the plugin, and don’t pollute the global namespace.

In the body of our jQuery plugin, we add a new function called \texttt{greenify()} to the \texttt{jQuery} object:

\begin{verbatim}
jQuery.fn.greenify = function() {
    this.css("color", "green");
    return this;
};
\end{verbatim}

\texttt{jQuery.fn} is the jQuery prototype object, the object that normal jQuery objects get all their methods from. By adding a method to this object, we enable any code that has a jQuery object to call our method on any HTML element or set of elements. For example, to turn all \texttt{<a>} elements on the page green you could do: \texttt{jQuery('a').greenify()}.

The code inside the \texttt{greenify()} function just calls jQuery’s standard \texttt{css()} method to set the CSS \texttt{color} attribute of the element to \texttt{green}. This is just standard jQuery code, except that within a custom jQuery function you use \texttt{this} to refer to the jQuery object, instead of using \texttt{\$} or \texttt{\$} (as you would normally do when calling jQuery methods from code external to jQuery).

Our method then returns \texttt{this} to allow jQuery method chaining to be used with our method. For example, a user can set an element’s CSS \texttt{color} attribute to \texttt{green} and add the CSS class \texttt{greenified} to the element in a single expression by chaining our jQuery method with another method: \texttt{\$('a').greenify().addClass('greenified')}.

Before we can use our \texttt{greenify()} method in CKAN, we need to import the \texttt{jquery.greenify.js} file into the CKAN page. To do this, add a \texttt{% resource %} tag to a template file, just as you would do to include any other JavaScript or CSS file in CKAN. Edit the \texttt{package_item.html} file:

\begin{verbatim}
{% ckan_extends %}
{% block content %}
{% super() %}
{% resource 'example_theme/example_theme_popover.js' %}
{% resource 'example_theme/example_theme_popover.css' %}
{% resource 'example_theme/jquery.greenify.js' %}

<button data-module="example_theme_popover"
    data-module-id="{{ package.id }}"
    data-module-title="{{ package.title }}"
    data-module-license-title="{{ package.license_title }}"
    data-module-num-resources="{{ package.num_resources }}">
    <i class="fa fa-info-circle"></i>
</button>
{% endblock %}
\end{verbatim}

Now we can call the \texttt{greenify()} method from our \texttt{example_theme_popover} JavaScript module. For example, we could add a line to the \texttt{_onClick()} method in \texttt{example_theme_popover.js} so that when a dataset info button is clicked it turns green:

\begin{verbatim}
_onClick: function(event) {
    // Make all the links on the page turn green.
    this.$('i').greenify();

    if (!this._snippetReceived) {

(continues on next page)
6.5.9 Internationalization

See Internationalizing strings in JavaScript code.

6.5.10 Testing JavaScript modules

Todo: Show how to write tests for the example module.

6.6 Best practices for writing CKAN themes

6.6.1 Don't use c

As much as possible, avoid accessing the Pylons template context c (or tmpl_context). c is a thread-global variable, which encourages spaghetti code that’s difficult to understand and to debug.

Instead, have controller methods add variables to the extra_vars parameter of render(), or have the templates call template helper functions instead.

extra_vars has the advantage that it allows templates, which are difficult to debug, to be simpler and shifts logic into the easier-to-test and easier-to-debug Python code. On the other hand, template helper functions are easier to reuse as they’re available to all templates and they avoid inconsistencies between the namespaces of templates that are rendered by different controllers (e.g. one controller method passes the package dict as an extra var named package, another controller method passes the same thing but calls it pkg, a third calls it pkg_dict).

You can use the ITemplateHelpers plugin interface to add custom helper functions, see Adding your own template helper functions.

6.6.2 Use url_for()

Always use url_for() (available to templates as h.url_for()) when linking to other CKAN pages, instead of hardcoding URLs like <a href="/dataset">. Links created with url_for() will update themselves if the URL routing changes in a new version of CKAN, or if a plugin changes the URL routing.

6.6.3 Use {% trans %},{% pluralize %},__() and ungettext()

All user-visible strings should be internationalized, see String internationalization.
6.6.4 Avoid name clashes

See Avoid name clashes.

6.6.5 JavaScript modules should have docstrings

A JavaScript module should have a docstring at the top of the file, briefly documenting what the module does and what options it takes. For example:

```javascript
"use strict";

/* example_theme_popover
 *
 * This JavaScript module adds a Bootstrap popover with some extra info about a
 * dataset to the HTML element that the module is applied to. Users can click
 * on the HTML element to show the popover.
 *
 * title - the title of the dataset
 * license - the title of the dataset’s copyright license
 * num_resources - the number of resources that the dataset has.
 *
 */
ckan.module('example_theme_popover', function ($) {
    return {
        initialize: function () {
            // Access some options passed to this JavaScript module by the calling
            // template.
            var num_resources = this.options.num_resources;
            var license = this.options.license;

            // Format a simple string with the number of resources and the license,
            // e.g. "3 resources, Open Data Commons Attribution License".
            var content = 'NUM resources, LICENSE'
                .replace('NUM', this.options.num_resources)
                .replace('LICENSE', this.options.license)

            // Add a Bootstrap popover to the HTML element (this.el) that this
            // JavaScript module was initialized on.
            this.el.popover({title: this.options.title,
                content: content,
                placement: 'left'});
        }
    };
});
```

6.6.6 JavaScript modules should unsubscribe from events in teardown()

Any JavaScript module that calls `this.sandbox.client.subscribe()` should have a `teardown()` function that calls `unsubscribe()`, to prevent memory leaks. CKAN calls the `teardown()` functions of modules when those modules are removed from the page.
6.6.7 Don’t overuse pubsub

There shouldn’t be very many cases where a JavaScript module really needs to use Pubsub, try to only use it when you really need to.

JavaScript modules in CKAN are designed to be small and loosely-coupled, for example modules don’t share any global variables and don’t call each other’s functions. But pubsub offers a way to tightly couple JavaScript modules together, by making modules depend on multiple events published by other modules. This can make the code buggy and difficult to understand.

6.6.8 Use `{% snippet %}`, not `{% include %}

Always use CKAN’s custom `{% snippet %}` tag instead of Jinja’s default `{% include %}` tag. Snippets can only access certain global variables, and any variables explicitly passed to them by the calling template. They don’t have access to the full context of the calling template, as included files do. This makes snippets more reusable, and much easier to debug.

6.6.9 Snippets should have docstrings

A snippet should have a docstring comment at the top of the file that briefly documents what the snippet does and what parameters it requires. For example:

```plaintext
#
Renders a list of the site's most popular groups.

groups - the list of groups to render
#
<h3>Most popular groups</h3>
<ul>
{% for group in groups %}
    <li>
        <a href="{{ h.url_for('group_read', action='read', id=group.name) }}">
            <h3>{{ group.display_name }}</h3>
        </a>
        {% if group.description %}
            <p>{{ h.markdown_extract(group.description, extract_length=80) }}</p>
        {% else %}
            <p>{{ _('This group has no description') }}</p>
        {% endif %}
        {% if group.package_count %}
            <strong>{{ ungettext('{num} Dataset', '{num} Datasets', group.package_count).format(num=group.package_count) }}</strong>
        {% else %}
            <span>{{ _('0 Datasets') }}</span>
        {% endif %}
    </li>
{% endfor %}
</ul>
```
6.7 Custom Jinja2 tags reference

Todo: TODO

6.8 Variables and functions available to templates

The following global variables and functions are available to all CKAN templates in their top-level namespace:

Note: In addition to the global variables listed below, each template also has access to variables from a few other sources:

- Any extra variables explicitly passed into a template by the controller that rendered the template will also be available to that template, in its top-level namespace. Any variables explicitly added to the template context variable `c` will also be available to the template as attributes of `c`.
  
  To see which additional global variables and context attributes are available to a given template, use CKAN’s debug footer.

- Any variables explicitly passed into a template snippet in the calling `{% snippet %}` tag will be available to the snippet in its top-level namespace. To see these variables, use the debug footer.

- Jinja2 also makes a number of filters, tests and functions available in each template’s global namespace. For a list of these, see the Jinja2 docs.

**tmpl_context**

The Pylons template context object, a thread-safe object that the application can store request-specific variables against without the variables associated with one HTTP request getting confused with variables from another request.

`tmpl_context` is usually abbreviated to `c` (an alias).

Using `c` in CKAN is discouraged, use template helper functions instead. See Don’t use `c`.

`c` is not available to snippets.

**c**

An alias for `tmpl_context`.

**app_globals**

The Pylons App Globals object, an instance of the `ckan.lib.app_globals.Globals` class. The application can store request-independent variables against the `app_globals` object. Variables stored against `app_globals` are shared between all HTTP requests.

**g**

An alias for `app_globals`.

**h**

CKAN’s template helper functions, plus any custom template helper functions provided by any extensions.

**request**

The Pylons Request object, contains information about the HTTP request that is currently being responded to, including the request headers and body, URL parameters, the requested URL, etc.
**response**

The **Pylons Response object**, contains information about the HTTP response that is currently being prepared to be sent back to the user, including the HTTP status code, headers, cookies, etc.

**session**

The **Beaker session object**, which contains information stored in the user’s currently active session cookie.

**_()**

The `pylons.i18n.translation.ugettext(value)` function:

Mark a string for translation. Returns the localized unicode string of value.

Mark a string to be localized as follows:

```
_('This should be in lots of languages')
```

**N_()**

The `pylons.i18n.translation.gettext_noop(value)` function:

Mark a string for translation without translating it. Returns value.

Used for global strings, e.g.:

```
foo = N_('Hello')

class Bar:
    def __init__(self):
        self.local_foo = _(foo)

h.set_lang('fr')
assert Bar().local_foo == 'Bonjour'

h.set_lang('es')
assert Bar().local_foo == 'Hola'
assert foo == 'Hello'
```

**ungettext()**

The `pylons.i18n.translation.ungettext(singular, plural, n)` function:

Mark a string for translation. Returns the localized unicode string of the pluralized value.

This does a plural-forms lookup of a message id. singular is used as the message id for purposes of lookup in the catalog, while n is used to determine which plural form to use. The returned message is a Unicode string.

Mark a string to be localized as follows:

```
umgettext('There is %(num)d file here', 'There are %(num)d files here', n) % {'num': n}
```

**translator**

An instance of the `gettext.NullTranslations` class. This is for internal use only, templates shouldn’t need to use this.

**class actions**

The `ckan.model.authz.Action` class.

**Todo:** Remove this? Doesn’t appear to be used and doesn’t look like something we want.
Objects and methods available to JavaScript modules

CKAN makes a few helpful objects and methods available for every JavaScript module to use, including:

- **this.el**, the HTML element that this instance of the object was initialized for. A jQuery element. See **this.options and this.el**.
- **this.options**, an object containing any options that were passed to the module via `data-module-*` attributes in the template. See **this.options and this.el**.
- **this.$()**, a jQuery find function that is scoped to the HTML element that the JavaScript module was applied to. For example, `this.$('a')` will return all of the `<a>` elements inside the module’s HTML element, *not* all of the `<a>` elements on the entire page.
  
  This is a shortcut for `this.el.find()`.

  jQuery provides many useful features in an easy-to-use API, including document traversal and manipulation, event handling, and animation. See jQuery’s own docs for details.

- **this.sandbox**, an object containing useful functions for all modules to use, including:
  
  - **this.sandbox.client**, an API client for calling the API
  
  - **this.sandbox.jQuery**, a jQuery find function that is not bound to the module’s HTML element. `this.sandbox.jQuery('a')` will return all the `<a>` elements on the entire page. Using `this.sandbox.jQuery` is discouraged, try to stick to `this.$` because it keeps JavaScript modules more independent.

  See JavaScript sandbox reference.

- A collection of **jQuery plugins**.

- **Pubsub functions** that modules can use to communicate with each other, if they really need to.

- Bootstrap’s JavaScript features, see the Bootstrap docs for details.

- The standard JavaScript **window** object. Using `window` in CKAN JavaScript modules is discouraged, because it goes against the idea of a module being independent of global context. However, there are some circumstances where a module may need to use `window` (for example if a vendor plugin that the module uses needs it).

- **this._** and **this.ngettext** for string internationalization. See Internationalization.

- **this.remove()**, a method that tears down the module and removes it from the page (this usually called by CKAN, not by the module itself).

Template helper functions reference

Helper functions

Consists of functions to typically be used within templates, but also available to Controllers. This module is available to templates as ‘h’.

```python
class ckan.lib.helpers.HelperAttributeDict(*args, **kwargs)

ckan.lib.helpers.core_helper(f, name=None)
    Register a function as a builtin helper method.

ckan.lib.helpers.redirect_to(*args, **kw)
    Issue a redirect: return an HTTP response with a 302 Moved header.
    This is a wrapper for routes.redirect_to() that maintains the user’s selected language when redirecting.
```
The arguments to this function identify the route to redirect to, they’re the same arguments as ckan.plugins.
toolkit.url_for() accepts, for example:

```python
import ckan.plugins.toolkit as toolkit

# Redirect to /dataset/my_dataset.
toolkit.redirect_to(controller='package', action='read',
                    id='my_dataset')
```

Or, using a named route:

```python
toolkit.redirect_to('dataset_read', id='changed')
```

If given a single string as argument, this redirects without url parsing

```python
toolkit.redirect_to('http://example.com')
toolkit.redirect_to('some/other/path')
```

ckan.lib.helpers.get_site_protocol_and_host()

Return the protocol and host of the configured ckan.site_url. This is needed to generate valid, full-qualified
URLs.

If ckan.site_url is set like this:

```python
ckan.site_url = http://example.com
```

Then this function would return a tuple (‘http’, ‘example.com’) If the setting is missing, (None, None) is returned
instead.

ckan.lib.helpers.url_for(*args, **kw)

Return the URL for an endpoint given some parameters.

This is a wrapper for flask.url_for() and routes.url_for() that adds some extra features that
CKAN needs.

To build a URL for a Flask view, pass the name of the blueprint and the view function separated by a period ., plus any URL parameters:

```python
url_for('api.action', ver=3, logic_function='status_show')
# Returns /api/3/action/status_show
```

For a fully qualified URL pass the _external=True parameter. This takes the ckan.site_url and
ckan.root_path settings into account:

```python
url_for('api.action', ver=3, logic_function='status_show',
       _external=True)
# Returns http://example.com/api/3/action/status_show
```

URLs built by Pylons use the Routes syntax:

```python
url_for(controller='package', action='read', id='my_dataset')
# Returns '/dataset/my_dataset'
```

Or, using a named route:

```python
url_for('dataset_read', id='changed')
# Returns '/dataset/changed'
```

Use qualified=True for a fully qualified URL when targeting a Pylons endpoint.
For backwards compatibility, an effort is made to support the Pylons syntax when building a Flask URL, but this support might be dropped in the future, so calls should be updated.

```python
ckan.lib.helpers.url_for_static(*args, **kw)
Returns the URL for static content that doesn’t get translated (eg CSS)
It’ll raise CkanUrlException if called with an external URL
This is a wrapper for routes.url_for()
```

```python
ckan.lib.helpers.url_for_static_or_external (*args, **kw)
Returns the URL for static content that doesn’t get translated (eg CSS), or external URLs
This is a wrapper for routes.url_for()
```

```python
ckan.lib.helpers.is_url(*args, **kw)
Returns True if argument parses as a http, https or ftp URL
```

```python
ckan.lib.helpers.url_is_local(url)
Returns True if url is local
```

```python
ckan.lib.helpers.full_current_url()
Returns the fully qualified current url (eg http://...) useful for sharing etc
```

```python
ckan.lib.helpers.current_url()
Returns current url unquoted
```

```python
ckan.lib.helpers.lang()
Return the language code for the current locale eg en
```

```python
ckan.lib.helpers.ckan_version()
Return CKAN version
```

```python
ckan.lib.helpers.lang_native_name(lang=None)
Return the language name currently used in it’s localised form either from parameter or current environ setting
```

```python
ckan.lib.helpers.is_rtl_language()
```

```python
ckan.lib.helpers.get_rtl_css()
```

```python
class ckan.lib.helpers.Message (category, message, allow_html)
A message returned by Flash.pop_messages().
Converting the message to a string returns the message text. Instances also have the following attributes:
- message: the message text.
- category: the category specified when the message was created.
```

```python
ckan.lib.helpers.flash_notice(message, allow_html=False)
Show a flash message of type notice
```

```python
ckan.lib.helpers.flash_error(message, allow_html=False)
Show a flash message of type error
```

```python
ckan.lib.helpers.flash_success(message, allow_html=False)
Show a flash message of type success
```

```python
ckan.lib.helpers.are_there_flash_messages()
Returns True if there are flash messages for the current user
```

```python
ckan.lib.helpers.nav_link (text, *args, **kwargs)
```

Parameters
- **class** – pass extra class(es) to add to the `<a>` tag
• **icon** – name of ckan icon to use within the link

• **condition** – if False then no link is returned

```python
ckan.lib.helpers.nav_link_flask(text, *args, **kwargs)
ckan.lib.helpers.nav_link_pylons(text, *args, **kwargs)
ckan.lib.helpers.build_nav_main(*args)
```
build a set of menu items.

args: tuples of (menu type, title) eg (`'login', _('Login')) outputs `<li><a href="...">title</a></li>`

```python
ckan.lib.helpers.build_nav_icon(menu_item, title, **kw)
```
Build a navigation item used for example in `user/read_base.html`.
Outputs `<li><a href="..."><i class="icon.."></i> title</a></li>`.

**Parameters**

• **menu_item (string)** – the name of the defined menu item defined in config/routing as the named route of the same name

• **title (string)** – text used for the link

• **kw** – additional keywords needed for creating url eg id=

**Return type** HTML literal

```python
ckan.lib.helpers.build_nav(menu_item, title, **kw)
```
Build a navigation item used for example breadcrumbs.
Outputs `<li><a href="...">title</a></li>`.

**Parameters**

• **menu_item (string)** – the name of the defined menu item defined in config/routing as the named route of the same name

• **title (string)** – text used for the link

• **kw** – additional keywords needed for creating url eg id=

**Return type** HTML literal

```python
ckan.lib.helpers.map_pylons_to_flask_route_name(menu_item)
```
returns flask routes for old fashioned route names

```python
ckan.lib.helpers.build_extra_admin_nav()
```
Build extra navigation items used in `admin/base.html` for values defined in the config option `ckan.admin_tabs`. Typically this is populated by extensions.

**Return type** HTML literal

```python
ckan.lib.helpers.default_group_type()
```

```python
ckan.lib.helpers.get_facet_items_dict(facet, limit=None, exclude_active=False)
```
Return the list of unselected facet items for the given facet, sorted by count.

Returns the list of unselected facet contraints or facet items (e.g. tag names like “russian” or “tolstoy”) for the given search facet (e.g. “tags”), sorted by facet item count (i.e. the number of search results that match each facet item).

Reads the complete list of facet items for the given facet from `c.search_facets`, and filters out the facet items that the user has already selected.
Arguments: facet – the name of the facet to filter. limit – the max. number of facet items to return. exclude_active – only return unselected facets.

`ckan.lib.helpers.has_more_facets(facet, limit=None, exclude_active=False)`

Returns True if there are more facet items for the given facet than the limit.

Reads the complete list of facet items for the given facet from `c.search_facets`, and filters out the facet items that the user has already selected.

Arguments: facet – the name of the facet to filter. limit – the max. number of facet items. exclude_active – only return unselected facets.

`ckan.lib.helpers.unselected_facet_items(facet, limit=10)`

Returns the list of unselected facet items for the given facet, sorted by count.

Reads the complete list of facet items for the given facet from `c.search_facets`, and filters out the facet items that the user has already selected.

Arguments: facet – the name of the facet to filter. limit – the max. number of facet items to return.

`ckan.lib.helpers.get_param_int(name, default=10)`

`ckan.lib.helpers.sorted_extras(package_extras, auto_clean=False, subs=None, exclude=None)`

Used for outputting package extras

Parameters

- `package_extras (dict)` – the package extras
- `auto_clean (bool)` – If true capitalize and replace -_ with spaces
- `subs (dict {'key': 'replacement'})` – substitutes to use instead of given keys
- `exclude (list of strings)` – keys to exclude

`ckan.lib.helpers.check_access(action, data_dict=None)`

`ckan.lib.helpers.linked_user(user, maxlength=0, avatar=20)`

`ckan.lib.helpers.group_name_to_title(name)`

`ckan.lib.helpers.markdown_extract(text, extract_length=190)`

return the plain text representation of markdown encoded text. That is the texted without any html tags. If extract_length is 0 then it will not be truncated.

`ckan.lib.helpers.icon_url(name)`

`ckan.lib.helpers.icon_html(url, alt=None, inline=True)`

`ckan.lib.helpers.icon(name, alt=None, inline=True)`

`ckan.lib.helpers.resource_icon(res)`

`ckan.lib.helpers.format_icon(_format)`

`ckan.lib.helpers.dict_list_reduce(list, key, unique=True)`

Take a list of dicts and create a new one containing just the values for the key with unique values if requested.

`ckan.lib.helpers.linked_gravatar(email_hash, size=100, default=None)`

`ckan.lib.helpers.gravatar(email_hash, size=100, default=None)`

`ckan.libhelpers.pager_url(page, partial=None, **kwargs)`

6.10. Template helper functions reference
class ckan.lib.helpers.Page(collection, page=1, items_per_page=20, item_count=None, 
sqlalchemy_session=None, presliced_list=False, url=None, 
**kwargs)

gerger(*args, **kwargs)
    Return string with links to other pages (e.g. “1 2 [3] 4 5 6 7”).

    **format:** Format string that defines how the pager is rendered. The string can contain the following $- 
tokens that are substituted by the string.Template module:
    • $first_page: number of first reachable page
    • $last_page: number of last reachable page
    • $page: number of currently selected page
    • $page_count: number of reachable pages
    • $items_per_page: maximal number of items per page
    • $first_item: index of first item on the current page
    • $last_item: index of last item on the current page
    • $item_count: total number of items
    • $link_first: link to first page (unless this is first page)
    • $link_last: link to last page (unless this is last page)
    • $link_previous: link to previous page (unless this is first page)
    • $link_next: link to next page (unless this is last page)

    To render a range of pages the token ‘~3~’ can be used. The number sets the radius of pages around 
the current page. Example for a range with radius 3:
    ‘1 .. 5 6 7 [8] 9 10 11 .. 500’
    Default: ‘~2~’

    **symbol_first** String to be displayed as the text for the %(link_first)s link above.
    Default: ‘<<’

    **symbol_last** String to be displayed as the text for the %(link_last)s link above.
    Default: ‘>>’

    **symbol_previous** String to be displayed as the text for the %(link_previous)s link above.
    Default: ‘<’

    **symbol_next** String to be displayed as the text for the %(link_next)s link above.
    Default: ‘>’

    **separator:** String that is used to separate page links/numbers in the above range of pages.
    Default: ‘ ’

    **page_param:** The name of the parameter that will carry the number of the page the user just 
clicked on. The parameter will be passed to a url_for() call so if you stay with the default ‘:controller/:action/:id’ routing and set page_param=’id’ then the :id part of the URL will be 
changed. If you set page_param=’page’ then url_for() will make it an extra parameters like ‘:con-
troller/:action/:id?page=1’. You need the page_param in your action to determine the page number 
the user wants to see. If you do not specify anything else the default will be a parameter called ‘page’. 
Note: If you set this argument and are using a URL generator callback, the callback must accept this name as an argument instead of ‘page’. callback, because the callback requires its argument to be ‘page’. Instead the callback itself can return any URL necessary.

**partial_param:** When using AJAX/AJAH to do partial updates of the page area the application has to know whether a partial update (only the area to be replaced) or a full update (reloading the whole page) is required. So this parameter is the name of the URL parameter that gets set to 1 if the ‘onclick’ parameter is used. So if the user requests a new page through a Javascript action (onclick) then this parameter gets set and the application is supposed to return a partial content. And without Javascript this parameter is not set. The application thus has to check for the existence of this parameter to determine whether only a partial or a full page needs to be returned. See also the examples in this modules docstring.

Default: ‘partial’

Note: If you set this argument and are using a URL generator callback, the callback must accept this name as an argument instead of ‘partial’.

**show_if_single_page:** if True the navigator will be shown even if there is only one page

Default: False

**link_attr (optional)** A dictionary of attributes that get added to A-HREF links pointing to other pages. Can be used to define a CSS style or class to customize the look of links.

Example: { ‘style’:’border: 1px solid green’ }

Default: { ‘class’:’pager_link’ }

**curpage_attr (optional)** A dictionary of attributes that get added to the current page number in the pager (which is obviously not a link). If this dictionary is not empty then the elements will be wrapped in a SPAN tag with the given attributes.

Example: { ‘style’:’border: 3px solid blue’ }

Default: { ‘class’:’pager_curpage’ }

**dotdot_attr (optional)** A dictionary of attributes that get added to the ‘..’ string in the pager (which is obviously not a link). If this dictionary is not empty then the elements will be wrapped in a SPAN tag with the given attributes.

Example: { ‘style’:’color: #808080’ }

Default: { ‘class’:’pager_dotdot’ }

**onclick (optional)** This parameter is a string containing optional Javascript code that will be used as the ‘onclick’ action of each pager link. It can be used to enhance your pager with AJAX actions loading another page into a DOM object.

In this string the variable ‘$partial_url’ will be replaced by the URL linking to the desired page with an added ‘partial=1’ parameter (or whatever you set ‘partial_param’ to). In addition the ‘$page’ variable gets replaced by the respective page number.

Note that the URL to the destination page contains a ‘partial_param’ parameter so that you can distinguish between AJAX requests (just refreshing the paginated area of your page) and full requests (loading the whole new page).

[Backward compatibility: you can use ‘%s’ instead of ‘$partial_url’]

**jQuery example:** “$('my-page-area').load('$partial_url'); return false;”

**Yahoo UI example:**
“YAHOO.util.Connect.asyncRequest(‘GET’, partial_url’, {
  success:function(o){YAHOO.util.Dom.get(‘#my-page-area’).innerHTML=o.responseText;}
 },null); return false;”

scriptaculous example:

return false;”

ExtJS example: “Ext.get(‘#my-page-area’).load({url: partial_url’}); return false;”

Custom example: “my_load_page($page)”

Additional keyword arguments are used as arguments in the links. Otherwise the link will be created with url_for() which points to the page you are currently displaying.

ckan.lib.helpers.get_page_number (params, key=’page’, default=1)

Return the page number from the provided params after verifying that it is an positive integer.

If it fails it will abort the request with a 400 error.

ckan.lib.helpers.get_display_timezone()

Returns a pytz timezone for the display_timezone setting in the configuration file or UTC if not specified. :rtype: timezone

ckan.lib.helpers.render_datetime (datetime, date_format=None, with_hours=False)

Render a datetime object or timestamp string as a localised date or in the requested format. If timestamp is badly formatted, then a blank string is returned.

Parameters

• datetime (datetime or ISO string format) – the date
• date_format (string) – a date format
• with_hours (bool) – should the hours:mins be shown

Return type string

ckan.lib.helpers.date_str_to_datetime(date_str)

Convert ISO-like formatted datestring to datetime object.

This function converts ISO format date- and datetime-strings into datetime objects. Times may be specified down to the microsecond. UTC offset or timezone information may not be included in the string.

Note - Although originally documented as parsing ISO date(-times), this function doesn’t fully adhere to the format. This function will throw a ValueError if the string contains UTC offset information. So in that sense, it is less liberal than ISO format. On the other hand, it is more liberal of the accepted delimiters between the values in the string. Also, it allows microsecond precision, despite that not being part of the ISO format.

ckan.lib.helpers.parse_rfc_2822_date (date_str, assume_utc=True)

Parse a date string of the form specified in RFC 2822, and return a datetime.

RFC 2822 is the date format used in HTTP headers. It should contain timezone information, but that cannot be relied upon.

If date_str doesn’t contain timezone information, then the ‘assume_utc’ flag determines whether we assume this string is local (with respect to the server running this code), or UTC. In practice, what this means is that if assume_utc is True, then the returned datetime is ‘aware’, with an associated tzinfo of offset zero. Otherwise, the returned datetime is ‘naive’.

If timezone information is available in date_str, then the returned datetime is ‘aware’, ie - it has an associated tz_info object.
Returns None if the string cannot be parsed as a valid datetime.

```python
ckan.lib.helpers.time_ago_from_timestamp(timestamp)
```

Returns a string like `5 months ago` for a datetime relative to now

- **param timestamp**: the timestamp or datetime
- **type timestamp**: string or datetime

**Return type**  string

```python
ckan.lib.helpers.button_attr(enable, type='primary')
```

**ckan.lib.helpers.dataset_display_name(package_or_package_dict)**

**ckan.lib.helpers.dataset_link(package_or_package_dict)**

**ckan.lib.helpers.resource_display_name(resource_dict)**

**ckan.lib.helpers.resource_link(resource_dict, package_id)**

**ckan.lib.helpers.tag_link(tag)**

**ckan.lib.helpers.group_link(group)**

**ckan.lib.helpers.organization_link(organization)**

**ckan.lib.helpers.dump_json(obj, **kw)**

**ckan.lib.helpers.auto_log_message()**

**ckan.lib.helpers.activity_div(template, activity, actor, object=None, target=None)**

**ckan.lib.helpers.snippet(template_name, **kw)**

This function is used to load html snippets into pages. Keywords can be used to pass parameters into the snippet rendering

**ckan.lib.helpers.convert_to_dict(object_type, objs)**

This is a helper function for converting lists of objects into lists of dicts. It is for backwards compatability only.

**ckan.lib.helpers.follow_button(obj_type, obj_id)**

Return a follow button for the given object type and id.

- If the user is not logged in return an empty string instead.

**Parameters**

- **obj_type(string)** – the type of the object to be followed when the follow button is clicked, e.g. ‘user’ or ‘dataset’

- **obj_id(string)** – the id of the object to be followed when the follow button is clicked

**Returns**  a follow button as an HTML snippet

**Return type**  string

**ckan.lib.helpers.follow_count(obj_type, obj_id)**

Return the number of followers of an object.

**Parameters**

- **obj_type(string)** – the type of the object, e.g. ‘user’ or ‘dataset’

- **obj_id(string)** – the id of the object

**Returns**  the number of followers of the object

**Return type**  int
ckan.lib.helpers.add_url_param(\(\text{alternative\_url}=\text{None}, \ \text{controller}=\text{None}, \ \text{action}=\text{None}, \ \text{extras}=\text{None}, \ \text{new\_params}=\text{None}\) )

Adds extra parameters to existing ones
controller action & extras (dict) are used to create the base url via \(\text{url\_for()}\) controller & action default to the current ones
This can be overriden providing an alternative_url, which will be used instead.

ckan.lib.helpers.remove_url_param(\(\text{key}, \ \text{value}=\text{None}, \ \text{replace}=\text{None}, \ \text{controller}=\text{None}, \ \text{action}=\text{None}, \ \text{extras}=\text{None}, \ \text{alternative\_url}=\text{None}\) )
Remove one or multiple keys from the current parameters. The first parameter can be either a string with the name of the key to remove or a list of keys to remove. A specific key/value pair can be removed by passing a second value argument otherwise all pairs matching the key will be removed. If replace is given then a new param key=replace will be added. Note that the value and replace parameters only apply to the first key provided (or the only one provided if key is a string).
controller action & extras (dict) are used to create the base url via \(\text{url\_for()}\) controller & action default to the current ones
This can be overriden providing an alternative_url, which will be used instead.

ckan.lib.helpers.include_resource(\(\text{resource}\) )
ckan.lib.helpers.urls_for_resource(\(\text{resource}\) )
Returns a list of urls for the resource specified. If the resource is a group or has dependencies then there can be multiple urls.
NOTE: This is for special situations only and is not the way to generally include resources. It is advised not to use this function.

ckan.lib.helpers.debug_inspect(\(\text{arg}\) )
Output \(\text{pprint.pformat}\) view of supplied arg

ckan.lib.helpers.popular(\(\text{type\_}, \ \text{number}=1, \ \text{min}=1, \ \text{title}=\text{None}\) )
display a popular icon.

ckan.lib.helpers.groups_available(\(\text{am\_member}=\text{False}\) )
Return a list of the groups that the user is authorized to edit.

Parameters \(\text{am\_member}\) – if True return only the groups the logged-in user is a member of, otherwise return all groups that the user is authorized to edit (for example, sysadmin users are authorized to edit all groups) (optional, default: False)

ckan.lib.helpers.organizations_available(\(\text{permission}='\text{manage\_group}', \ \text{include\_dataset\_count}=\text{False}\) )
Return a list of organizations that the current user has the specified permission for.

ckan.lib.helpers.roles_translated()
Return a dict of available roles with their translations

ckan.lib.helpers.user_in_org_or_group(\(\text{group\_id}\) )
Check if user is in a group or organization

ckan.lib/helpers.dashboard_activity_stream(\(\text{user\_id}, \ \text{filter\_type}=\text{None}, \ \text{filter\_id}=\text{None}, \ \text{offset}=0\) )
Return the dashboard activity stream of the current user.

Parameters

- \(\text{user\_id}(\text{string})\) – the id of the user
- \(\text{filter\_type}(\text{string})\) – the type of thing to filter by
- \(\text{filter\_id}(\text{string})\) – the id of item to filter by
Returns an activity stream as an HTML snippet

Return type  string

ckan.lib.helpers.recently_changed_packages_activity_stream(limit=None)

ckan.lib.helpers.escape_js(str_to_escape)
Escapes special characters from a JS string.

Useful e.g. when you need to pass JSON to the templates

Parameters  str_to_escape – string to be escaped

Return type  string

ckan.lib.helpers.escape_js(str_to_escape)

ckan.lib.helpers.get_pkg_dict_extra(pkg_dict, key, default=None)

Returns the value for the dataset extra with the provided key.

If the key is not found, it returns a default value, which is None by default.

Parameters  pkg_dict – dictized dataset

Key  extra key to lookup

Default  default value returned if not found

ckan.lib.helpers.get_request_param(parameter_name, default=None)

This function allows templates to access query string parameters from the request. This is useful for things like sort order in searches.

ckan.lib.helpers.html_auto_link(data)

Linkifies HTML

- tag converted to a tag link
- dataset converted to a dataset link
- group converted to a group link
- http:// converted to a link

ckan.lib.helpers.render_markdown(data, auto_link=True, allow_html=False)

Returns the data as rendered markdown

Parameters

- auto_link (bool) – Should ckan specific links be created e.g. group:xxx
- allow_html (bool) – If True then html entities in the markdown data. This is dangerous if users have added malicious content. If False all html tags are removed.

ckan.lib.helpers.format_resource_items(items)

Take a resource item list and format nicely with blacklisting etc.

ckan.lib.helpers.resource_preview(resource, package)

Returns a rendered snippet for a embedded resource preview.

Depending on the type, different previews are loaded. This could be an img tag where the image is loaded directly or an iframe that embeds a web page or a recline preview.

ckan.lib.helpers.get_allowed_view_types(resource, package)

ckan.lib.helpers.rendered_resource_view(resource_view, resource, package, embed=False)

Returns a rendered resource view snippet.

ckan.lib.helpers.view_resource_url(resource_view, resource, package, **kw)

Returns url for resource. made to be overridden by extensions. i.e by resource proxy.
ckan.lib.helpers.resource_view_is_filterable(resource_view)
    Returns True if the given resource view support filters.

ckan.lib.helpers.resource_view_get_fields(resource)
    Returns sorted list of text and time fields of a datastore resource.

ckan.lib.helpers.resource_view_is_iframed(resource_view)
    Returns true if the given resource view should be displayed in an iframe.

ckan.lib.helpers.resource_view_icon(resource_view)
    Returns the icon for a particular view type.

ckan.lib.helpers.resource_view_display_preview(resource_view)
    Returns if the view should display a preview.

ckan.lib.helpers.resource_view_full_page(resource_view)
    Returns if the edit view page should be full page.

ckan.lib.helpers.remove_linebreaks(string)
    Remove linebreaks from string to make it usable in JavaScript

ckan.lib.helpers.list_dict_filter(list_, search_field, output_field, value)
    Takes a list of dicts and returns the value of a given key if the item has a matching value for a supplied key

    Parameters
    - list (list of dicts) – the list to search through for matching items
    - search_field (string) – the key to use to find matching items
    - output_field (string) – the key to use to output the value
    - value – the value to search for

ckan.lib.helpers.SI_number_span(number)
    outputs a span with the number in SI unit eg 14700 -> 14.7k

ckan.lib.helpers.new_activities()
    Return the number of activities for the current user.
    See logic.action.get.dashboard_new_activities_count() for more details.

ckan.lib.helpers.uploads_enabled()

ckan.lib.helpers.get_featured_organizations(count=1)
    Returns a list of favourite organization in the form of organization_list action function

ckan.lib.helpers.get_featured_groups(count=1)
    Returns a list of favourite group the form of organization_list action function

ckan.lib.helpers.featured_group_org(items, get_action, list_action, count)

ckan.lib.helpers.get_site_statistics()

ckan.lib.helpers.resource_formats()
    Returns the resource formats as a dict, sourced from the resource format JSON file.

    Parameters
    - key – potential user input value
    - value – [canonical mimetype lowercased, canonical format (lowercase), human readable form]

    Fuller description of the fields are described in ckan/config/resource_formats.json.

ckan.lib.helpers.unified_resource_format(format)
ckan.lib.helpers.check_config_permission(permission)
ckan.lib.helpers.get_organization(org=None, include_datasets=False)
ckan.lib.helpers.license_options(existing_license_id=None)
    Returns [(l.title, l.id), ...] for the licenses configured to be offered. Always includes the existing_license_id, if supplied.
ckan.lib.helpers.get_translated(data_dict, field)
ckan.lib.helpers.facets()
    Returns a list of the current facet names
ckan.lib.helpers.mail_to(email_address, name)
ckan.lib.helpers.radio(selected, id, checked)
ckan.lib.helpers.clean_html(html)
ckan.lib.helpers.load_plugin_helpers()
    (Re)loads the list of helpers provided by plugins.
ckan.lib.helpers.sanitize_id(id_)
    Given an id (uuid4), if it has any invalid characters it raises ValueError.

6.11 Template snippets reference

Todo: Autodoc all the default template snippets here. This probably means writing a Sphinx plugin.

6.12 JavaScript sandbox reference

Todo: Autodoc the JavaScript sandbox. This will probably require writing a custom Sphinx plugin.

6.13 JavaScript API client reference

Todo: Autodoc the JavaScript client. This will probably require writing a custom Sphinx plugin.

6.14 CKAN jQuery plugins reference

CKAN adds a number of custom plugins that can be accessed by JavaScript modules via this.sandbox.jQuery.
Contributing guide

CKAN is free open source software and contributions are welcome, whether they’re bug reports, source code, documentation or translations. The following sections will walk you through our processes for making different kinds of contributions to CKAN:

7.1 Reporting issues

If you’ve found a bug in CKAN, open a new issue on CKAN’s GitHub Issues (try searching first to see if there’s already an issue for your bug).

If you can fix the bug yourself, please send a pull request!

Do not use an issue to ask how to do something - for that use StackOverflow with the ‘ckan’ tag.

Do not use an issue to suggest an significant change to CKAN - instead create an issue at https://github.com/ckan/ideas-and-roadmap.

7.1.1 Writing a good issue

- Describe what went wrong
- Say what you were doing when it went wrong
- If in doubt, provide detailed steps for someone else to recreate the problem.
- A screenshot is often helpful
- If it is a 500 error / ServerError / exception then it’s essential to supply the full stack trace provided in the CKAN log.
7.1.2 Issues process

The CKAN Technical Team reviews new issues twice a week. They aim to assign someone on the Team to take responsibility for it. These are the sorts of actions to expect:

- If it is a serious bug and the person who raised it won’t fix it then the Technical Team will aim to create a fix.
- A feature that you plan to code shortly will be happily discussed. It’s often good to get the team’s support for a feature before writing lots of code. You can then quote the issue number in the commit messages and branch name. (Larger changes or suggestions by non-contributers are better discussed on https://github.com/ckan/ideas-and-roadmap instead)
- Features may be marked “Good for Contribution” which means the Team is happy to see this happen, but the Team are not offering to do it.

7.1.3 Old issues

If an issue has little activity for 12 months then it should be closed. If someone is still keen for it to happen then they should comment, re-open it and push it forward.

7.2 Translating CKAN

CKAN is used in many countries, and adding a new language to the web interface is a simple process.

CKAN uses the url to determine which language is used. An example would be /fr/dataset would be shown in French. If CKAN is running under a directory then an example would be /root/fr/dataset. For custom paths check the ckan.root_path config option.

See also:

Developers, see String internationalization for how to mark strings for translation in CKAN code.

7.2.1 Supported languages

CKAN already supports numerous languages. To check whether your language is supported, look in the source at ckan/i18n for translation files. Languages are named using two-letter ISO language codes (e.g. es, de).

If your language is present, you can switch the default language simply by setting the ckan.locale_default option in your CKAN config file, as described in Internationalisation Settings. For example, to switch to German:

```
ckan.locale_default=de
```

See also:

Internationalisation Settings

If your language is not supported yet, the remainder of this section section provides instructions on how to prepare a translation file and add it to CKAN.

7.2.2 Adding a new language or improving an existing translation

If you want to add an entirely new language to CKAN or update an existing translation, you have two options.
• **Transifex setup.** Creating or updating translation files using Transifex, the open source translation software. To add a language you need to request it from the Transifex dashboard: [https://www.transifex.com/okfn/ckan/dASHBOARD/](https://www.transifex.com/okfn/ckan/dASHBOARD/) Alternatively to update an existing language you need to request to join the appropriate CKAN language team. If you don’t hear back from the CKAN administrators, contact them via the ckan-dev list.

• **Manual setup.** Creating translation files manually in your own branch.

**Note:** If you choose not to contribute your translation back via Transifex then you must ensure you make it public in another way, as per the requirements of CKAN’s AGPL license.

---

**Transifex setup**

Transifex, the open translation platform, provides a simple web interface for writing translations and is widely used for CKAN internationalization.

Using Transifex makes it easier to handle collaboration, with an online editor that makes the process more accessible.

Existing CKAN translation projects can be found at: [https://www.transifex.com/okfn/ckan/content/](https://www.transifex.com/okfn/ckan/content/)

When leading up to a CKAN release, the strings are loaded onto Transifex and ckan-dev list is emailed to encourage translation work. When the release is done, the latest translations on Transifex are checked back into CKAN.

**Transifex administration**

The Transifex workflow is described in the *Doing a CKAN release* page.

**Manual setup**

**Note:** Please keep the CKAN core developers aware of new languages created in this way.

All the English strings in CKAN are extracted into the `ckan.pot` file, which can be found in `ckan/i18n`.

**Note:** For information, the pot file was created with the `babel` command `python setup.py extract_messages`.

---

1. **Preparation**

This tutorial assumes you’ve got CKAN installed as source in a virtualenv. Activate the virtualenv and cd to the ckan directory:

```
. /usr/lib/ckan/default/bin/activate
cd /usr/lib/ckan/default/src/ckan
```

2. **Install Babel**

You need Python’s `babel` library (Debian package `python-pybabel`). Install it as follows with pip:
pip install --upgrade Babel

3. Create a ‘PO’ file for your language

Then create a translation file for your language (a PO file) using the pot file (containing all the English strings):

```bash
git add ckan/i18n/YOUR_LANGUAGE/LC_MESSAGES/ckan.po
```

Replace `YOUR_LANGUAGE` with the two-letter ISO language code (e.g. es, de).

In future, when the pot file is updated, you can update the strings in your po file, while preserving your po edits, by doing:

```bash
git commit -m '[i18n]: New language po added: YOUR_LANGUAGE' ckan/i18n/YOUR_LANGUAGE/
```

NB: It is not appropriate to do a Pull Request to the main ckan repo, since that takes its translations from Transifex.

2. Do the translation

Edit the po file and translate the strings. For more information on how to do this, see the Pylons book.

We recommend using a translation tool, such as poedit, to check the syntax is correct. There are also extensions for editors such as emacs.

3. Commit the translation

When the po is complete, create a branch in your source, then commit it to your own fork of the CKAN repo:

```bash
git add ckan/i18n/YOUR_LANGUAGE/LC_MESSAGES/ckan.po
git commit -m '[i18n]: New language po added: YOUR_LANGUAGE' ckan/i18n/YOUR_LANGUAGE/
```

4. Compile a translation

Once you have created a translation (either with Transifex or manually) you can build the po file into a mo file, ready for deployment.

With either method of creating the po file, it should be found in the CKAN i18n repository: ckan/i18n/YOUR_LANGUAGE/LC_MESSAGES/ckan.po

In this repo, compile the po file like this:

```bash
git add ckan/i18n/YOUR_LANGUAGE/LC_MESSAGES/ckan.po
git commit -m '[i18n]: New language po added: YOUR_LANGUAGE' ckan/i18n/YOUR_LANGUAGE/
```

As before, replace `YOUR_LANGUAGE` with your language short code, e.g. es, de.

This will result in a binary ‘mo’ file of your translation at ckan/i18n/YOUR_LANGUAGE/LC_MESSAGES/ckan.mo.
5. (optional) Deploy the translation

This section explains how to deploy your translation to your CKAN server.

Once you have a compiled translation file, copy it to your host:

```
scp ckan.mo /usr/lib/ckan/default/src/ckan/ckan/i18n/hu/LC_MESSAGES/ckan.
```

Adjust the path if you did not use the default location. This example is for language hu.

6. Configure the language

Finally, once the mo file is in place, you can switch between the installed languages using the `ckan.locale` option in the CKAN config file, as described in *Internationalisation Settings*.

### 7.2.3 Translations management policy

One of the aims of CKAN is to be accessible to the greatest number of users. Translating the user interface to as many languages as possible plays a huge part in this, and users are encouraged to contribute to the existing translations or submit a new one. At the same time we need to ensure the stability between CKAN releases, so the following guidelines apply when managing translations:

- About 3 weeks before a CKAN release, CKAN is branched, and the English strings are frozen, and an announcement is made on ckan-dev to call for translation work. Translators are given 2 weeks to translate any new strings in this release.
- During this period, translation is done on a ‘resource’ on Transifex which is named to match the new CKAN version. It has been created as a copy of the next most recent resource, so any new languages creation or other updates (done on Transifex since the last release) automatically go into the new release.

### 7.3 Testing CKAN

If you’re a CKAN developer, if you’re developing an extension for CKAN, or if you’re just installing CKAN from source, you should make sure that CKAN’s tests pass for your copy of CKAN. This section explains how to run CKAN’s tests.

CKAN’s testsuite contains automated tests for both the back-end (Python) and the front-end (JavaScript). In addition, the correct functionality of the complete front-end (HTML, CSS, JavaScript) on all supported browsers should be tested manually.

See also:

*CKAN coding standards for tests*  Conventions for writing tests for CKAN

#### 7.3.1 Back-end tests

Most of CKAN’s testsuite is for the backend Python code.
Install additional dependencies

Some additional dependencies are needed to run the tests. Make sure you’ve created a config file at /etc/ckan/default/development.ini, then activate your virtual environment:

```
. /usr/lib/ckan/default/bin/activate
```

Install nose and other test-specific CKAN dependencies into your virtual environment:

```
pip install -r /usr/lib/ckan/default/src/ckan/dev-requirements.txt
```

Set up the test databases

Create test databases:

```
sudo -u postgres createdb -O ckan_default ckan_test -E utf-8
sudo -u postgres createdb -O ckan_default datastore_test -E utf-8
```

Set the permissions:

```
paster datastore set-permissions -c test-core.ini | sudo -u postgres psql
```

This database connection is specified in the `test-core.ini` file by the `sqlalchemy.url` parameter.

You should also make sure that the Redis database configured in `test-core.ini` is different from your production database.

Configure Solr Multi-core

The tests assume that Solr is configured ‘multi-core’, whereas the default Solr set-up is often ‘single-core’. You can ask Solr for its cores status:

```
curl -s 'http://127.0.0.1:8983/solr/admin/cores?action=STATUS' | python -c 'import sys; import xml.dom.minidom; s=sys.stdin.read(); print xml.dom.minidom.parseString(s).toprettyxml()'
```

Each core will be within a child from the `<lst name="status"` element, and contain a `<str name="instanceDir">` element.

You can also tell from your ckan config (assuming ckan is working):

```
grep solr_url /etc/ckan/default/production.ini
# single-core: solr_url = http://127.0.0.1:8983/solr
# multi-core: solr_url = http://127.0.0.1:8983/solr/ckan
```

To enable multi-core:

1. Find the `instanceDir` of the existing Solr core. It is found in the output of the curl command above.
   e.g. `/usr/share/solr/ or /opt/solr/example/solr/collection1`

2. Make a copy of that core’s directory e.g.:

```
sudo cp -r /usr/share/solr/ /etc/solr/ckan
```

3. Find your `solr.xml`. It is in the Solr Home directory given by this command:

```
curl -s 'http://127.0.0.1:8983/solr/admin/' | grep SolrHome
```
4. Configure Solr with the new core by editing `solr.xml`. The ‘cores’ section will have one ‘core’ in it already and needs the second one ‘ckan’ added so it looks like this:

```xml
<cores adminPath="/admin/cores" defaultCoreName="collection1">
  <core name="collection1" instanceDir="." />
  <core name="ckan" instanceDir="/etc/solr/ckan" />
</cores>
```

5. Restart Solr by restarting Jetty (or Tomcat):

```
sudo service jetty restart
```

6. Edit your main ckan config (e.g. `/etc/ckan/default/development.ini`) and adjust the `solr_url` to match:

```
solr_url = http://127.0.0.1:8983/solr/ckan
```

### Run the tests

To run CKAN’s tests using PostgreSQL as the database, you have to give the `--with-pylons=test-core.ini` option on the command line. This command will run the tests for CKAN core and for the core extensions:

```
nosetests --ckan --with-pylons=test-core.ini ckan ckanext
```

The speed of the PostgreSQL tests can be improved by running PostgreSQL in memory and turning off durability, as described in the PostgreSQL documentation.

By default the tests will keep the database between test runs. If you wish to drop and reinitialize the database before the run you can use the `reset-db` option:

```
nosetests --ckan --reset-db --with-pylons=test-core.ini ckan
```

### Migration testing

If you’re a CKAN developer or extension developer and your new code requires a change to CKAN’s model, you’ll need to write a migration script. To ensure that the migration script itself gets tested, you should run the tests with the `--ckan-migration` option, for example:

```
nosetests --ckan --ckan-migration --with-pylons=test-core.ini ckan ckanext
```

By default tests are run using the model defined in `ckan/model`. With the `--ckan-migration` option the tests will run using a database that has been created by running the migration scripts in `ckan/migration`, which is how the database is created and upgraded in production.

**Warning:** A common error when wanting to run tests against a particular database is to change `sqlalchemy.url` in `test.ini` or `test-core.ini`. The problem is that these are versioned files and people have checked in these by mistake, creating problems for other developers.

### Common error messages
ConfigError

`nose.config.ConfigError: Error reading config file 'setup.cfg': no such option 'with-pylons'`

This error can result when you run nosetests for two reasons:

1. Pylons nose plugin failed to run. If this is the case, then within a couple of lines of running `nosetests` you’ll see this warning: *Unable to load plugin pylons* followed by an error message. Fix the error here first.
2. The Python module `’Pylons’` is not installed into you Python environment. Confirm this with:

   ```
   python -c "import pylons"
   ```

OperationalError

`OperationalError: (OperationalError) no such function: plainto_tsquery ...`

This error usually results from running a test which involves search functionality, which requires using a PostgreSQL database, but another (such as SQLite) is configured. The particular test is either missing a `@search_related` decorator or there is a mixup with the test configuration files leading to the wrong database being used.

nosetests

`nosetests: error: no such option: --ckan` Nose is either unable to find `ckan/ckan_nose_plugin.py` in the python environment it is running in, or there is an error loading it. If there is an error, this will surface it:

```
nopsetests --version
```

There are a few things to try to remedy this:

Commonly this is because the nosetests isn’t running in the python environment. You need to have nose actually installed in the python environment. To see which you are running, do this:

```
which nosetests
```

If you have activated the environment and this still reports `/usr/bin/nosetests` then you need to:

```
pip install --ignore-installed nose
```

If `nose --version` still fails, ensure that `ckan` is installed in your environment:

```
cd /usr/lib/ckan/default/src/ckan
python setup.py develop
```

One final check - the version of nose should be at least 1.0. Check with:

```
pip freeze | grep -i nose
```

SolrError

328 Chapter 7. Contributing guide`
This means your solr_url is not corresponding with your SOLR. When running tests, it is usually easiest to change your set-up to match the default solr_url in test-core.ini. Often this means switching to multi-core - see Configure Solr Multi-core.

### 7.3.2 Front-end tests

Front-end testing consists of both automated tests (for the JavaScript code) and manual tests (for the complete front-end consisting of HTML, CSS and JavaScript).

#### Automated JavaScript tests

The JS tests are written using the Mocha test framework and run via PhantomJS. First you need to install the necessary packages:

```bash
sudo apt-get install npm nodejs-legacy
sudo npm install -g mocha-phantomjs@3.5.0 phantomjs@~1.9.1
```

To run the tests, make sure that a test server is running:

```bash
. /usr/lib/ckan/default/bin/activate
paster serve test-core.ini
```

Once the test server is running switch to another terminal and execute the tests:

```bash
```

#### Manual tests

All new CKAN features should be coded so that they work in the following browsers:

- Internet Explorer: 11, 10, 9 & 8
- Firefox: Latest + previous version
- Chrome: Latest + previous version

These browsers are determined by whatever has >= 1% share with the latest months data from: [http://data.gov.uk/data/site-usage](http://data.gov.uk/data/site-usage)

#### Install browser virtual machines

In order to test in all the needed browsers you’ll need access to all the above browser versions. Firefox and Chrome should be easy whatever platform you are on. Internet Explorer is a little trickier. You’ll need Virtual Machines.

We suggest you use [https://github.com/xdissent/ievms](https://github.com/xdissent/ievms) to get your Internet Explorer virtual machines.
Testing methodology

Firstly we have a primer page. If you’ve touched any of the core front-end code you’ll need to check if the primer is rendering correctly. The primer is located at: http://localhost:5000/testing/primer

Secondly whilst writing a new feature you should endeavour to test in at least in your core browser and an alternative browser as often as you can.

Thirdly you should fully test all new features that have a front-end element in all browsers before making your pull request into CKAN master.

Common front-end pitfalls & their fixes

Here’s a few of the most common front end bugs and a list of their fixes.

Reserved JS keywords

Since IE has a stricter language definition in JS it really doesn’t like you using JS reserved keywords method names, variables, etc… This is a good list of keywords not to use in your JavaScript:

```
/* These are bad */
var a = {
    default: 1,
    delete: function() {}
};

/* These are good */
var a = {
    default_value: 1,
    remove: function() {}
};
```

Unclosed JS arrays / objects

Internet Explorer doesn’t like it’s JS to have unclosed JS objects and arrays. For example:

```
/* These are bad */
var a = {
    b: 'c',
};
var a = ['b', 'c', ];

/* These are good */
var a = {
    c: 'c'
};
var a = ['b', 'c'];
```
7.4 Writing commit messages

We use the version control system git for our code and documentation, so when contributing code or docs you’ll have to commit your changes to git and write a git commit message. Generally, follow the commit guidelines from the Pro Git book:

- Try to make each commit a logically separate, digestible changeset.
- The first line of the commit message should concisely summarise the changeset.
- Optionally, follow with a blank line and then a more detailed explanation of the changeset.
- Use the imperative present tense as if you were giving commands to the codebase to change its behaviour, e.g. Add tests for..., make xyzzy do frotz..., this helps to make the commit message easy to read.

If your commit has an issue in the CKAN issue tracker put the issue number at the start of the first line of the commit message like this: [#123]. This makes the CKAN release manager’s job much easier!

Here’s an example of a good CKAN commit message:

```plaintext
[#607] Allow reactivating deleted datasets

Currently if a dataset is deleted and users navigate to the edit form, there is no state field and the delete button is still shown.

After this change, the state dropdown is shown if the dataset state is not active, and the delete button is not shown.
```

7.5 Making a pull request

Once you’ve written some CKAN code or documentation, you can submit it for review and merge into the central CKAN git repository by making a pull request. This section will walk you through the steps for making a pull request.

1. Create a git branch

   Each logically separate piece of work (e.g. a new feature, a bug fix, a new docs page, or a set of improvements to a docs page) should be developed on its own branch forked from the master branch.

   The name of the branch should include the issue number (if this work has an issue in the CKAN issue tracker), and a brief one-line synopsis of the work, for example:

   2298-add-sort-by-controls-to-search-page

2. Fork CKAN on GitHub

   Sign up for a free account on GitHub and fork CKAN, so that you have somewhere to publish your work.

   Add your CKAN fork to your local CKAN git repo as a git remote. Replace USERNAME with your GitHub username:

   ```
   git remote add my_fork https://github.com/USERNAME/ckan
   ```

3. Commit and push your changes

   Commit your changes on your feature branch, and push your branch to GitHub. For example, make sure you’re currently on your feature branch then run these commands:
When writing your git commit messages, try to follow the Writing commit messages guidelines.

4. Send a pull request

Once your work on a branch is complete and is ready to be merged into the master branch, create a pull request on GitHub. A member of the CKAN team will review your work and provide feedback on the pull request page. The reviewer may ask you to make some changes. Once your pull request has passed the review, the reviewer will merge your code into the master branch and it will become part of CKAN!

When submitting a pull request:

- Your branch should contain one logically separate piece of work, and not any unrelated changes.
- You should have good commit messages, see Writing commit messages.
- Your branch should contain new or changed tests for any new or changed code, and all the CKAN tests should pass on your branch, see Testing CKAN.
- Your pull request shouldn’t lower our test coverage. You can check it at our coveralls page <https://coveralls.io/r/ckan/ckan>. If for some reason you can’t avoid lowering it, explain why on the pull request.
- Your branch should contain new or updated documentation for any new or updated code, see Writing documentation.
- Your branch should be up to date with the master branch of the central CKAN repo, so pull the central master branch into your feature branch before submitting your pull request.

For long-running feature branches, it’s a good idea to pull master into the feature branch periodically so that the two branches don’t diverge too much.

7.6 Reviewing and merging a pull request

Of course it’s not possible to give an exact recipe for reviewing a pull request, you simply have to assess the code and decide whether you’re happy with it. Nonetheless, here is an incomplete list of things to look for:

- Does the pull request contain one logically separate piece of work (e.g. one new feature, bug fix, etc. per pull request)?
- Does the pull request follow the guidelines for writing commit messages?
- Is the branch up to date - have the latest commits from master been pulled into the branch?
- Does the pull request contain new or updated tests for any new or updated code, and do the tests follow CKAN’s testing coding standards?
- Do all the CKAN tests pass, on the new branch?
- Does the pull request contain new or updated docs for any new or updated features, and do the docs follow CKAN’s documentation guidelines?
- Does the new code follow CKAN’s code architecture and the various coding standards for Python, JavaScript, etc.?
- If the new code contains changes to the database schema, does it have a database migration?
• Does the code contain any changes that break backwards-incompatibility? If so, is the breakage necessary or do the benefits of the change justify the breakage? Have the breaking changes been added to the changelog?

Backwards-compability needs to be considered when making changes that break the interfaces that CKAN provides to third-party code, including API clients, plugins and themes.

In general, any code that’s documented in the reference sections of the API, extensions or theming needs to be considered. For example this includes changes to the API actions, the plugin interfaces or plugins toolkit, the converter and validator functions (which are used by plugins), the custom Jinja2 tags and variables available to Jinja templates, the template helper functions, the core template files and their blocks, the sandbox available to JavaScript modules (including custom jQuery plugins and the JavaScript CKAN API client), etc.

• Does the new code add any dependencies to CKAN (e.g. new third-party Python modules imported)? If so, is the new dependency justified and has it been added following the right process? See Upgrading CKAN’s dependencies.

7.6.1 Merging a pull request

Once you’ve reviewed a pull request and you’re happy with it, you need to merge it into the master branch. You should do this using the --no-ff option in the git merge command. For example:

```
git checkout feature-branch
git pull origin feature-branch
git checkout master
git pull origin master
git merge --no-ff feature-branch
git push origin master
```

Before doing the git push, it’s a good idea to check that all the tests are passing on your master branch (if the latest commits from master have already been pulled into the feature branch on github, then it may be enough to check that all tests passed for the latest commit on this branch on Travis).

Also before doing the git push, it’s a good idea to use git log and/or git diff to check the difference between your local master branch and the remote master branch, to make sure you only push the changes you intend to push:

```
git log ...origin/master
git diff ..origin/master
```

7.7 Writing documentation

This section gives some guidelines to help us to write consistent and good quality documentation for CKAN.

Documentation isn’t source code, and documentation standards don’t need to be followed as rigidly as coding standards do. In the end, some documentation is better than no documentation, it can always be improved later. So the guidelines below are soft rules.

Having said that, we suggest just one hard rule: no new feature (or change to an existing feature) should be missing from the docs (but see todo).

See also:

Jacob Kaplan-Moss’s Writing Great Documentation A series of blog posts about writing technical docs, a lot of our guidelines were based on this.
See also:

The quickest and easiest way to contribute documentation to CKAN is to sign up for a free GitHub account and simply edit the CKAN Wiki. Docs started on the wiki can make it onto docs.ckan.org later. If you do want to contribute to docs.ckan.org directly, follow the instructions on this page.

Tip: Use the reStructuredText markup format when creating a wiki page, since reStructuredText is the format that docs.ckan.org uses, this will make moving the documentation from the wiki into docs.ckan.org later easier.

### 7.7.1 Getting started

This section will walk you through downloading the source files for CKAN’s docs, editing them, and submitting your work to the CKAN project.

CKAN’s documentation is created using Sphinx, which in turn uses Docutils (reStructuredText is part of Docutils). Some useful links to bookmark:

- Sphinx’s reStructuredText Primer
- reStructuredText cheat sheet
- reStructuredText quick reference
- Sphinx Markup Constructs is a full list of the markup that Sphinx adds on top of Docutils.

The source files for the docs are in the doc directory of the CKAN git repo. The following sections will walk you through the process of making changes to these source files, and submitting your work to the CKAN project.

#### Install CKAN into a virtualenv

Create a Python virtual environment (virtualenv), activate it, install CKAN into the virtual environment, and install the dependencies necessary for building CKAN. In this example we’ll create a virtualenv in a folder called `pyenv`. Run these commands in a terminal:

```
virtualenv --no-site-packages pyenv
. pyenv/bin/activate
pip install -e 'git+https://github.com/ckan/ckan.git#egg=ckan'
cd pyenv/src/ckan/
pip install -r dev-requirements.txt
pip install -r requirements.txt
```

#### Build the docs

You should now be able to build the CKAN documentation locally. Make sure your virtual environment is activated, and then run this command:

```
python setup.py build_sphinx
```

Now you can open the built HTML files in `build/sphinx/html`, e.g.:

```
firefox build/sphinx/html/index.html
```
Edit the reStructuredText files

To make changes to the documentation, use a text editor to edit the .rst files in doc/. Save your changes and then build the docs again (python setup.py build_sphinx) and open the HTML files in a web browser to preview your changes.

Once your docs are ready to submit to the CKAN project, follow the steps in Making a pull request.

7.7.2 How the docs are organized

It’s important that the docs have a clear, simple and extendable structure (and that we keep it that way as we add to them), so that both readers and writers can easily answer the questions: If you need to find the docs for a particular feature, where do you look? If you need to add a new page to the docs, where should it go?

As /index explains, the documentation is organized into several guides, each for a different audience: a user guide for web interface users, an extending guide for extension developers, a contributing guide for core contributors, etc. These guides are ordered with the simplest guides first, and the most advanced last.

In the source, each one of these guides is a subdirectory with its own index.rst containing its own .. toctree:: directive that lists all of the other files in that subdirectory. The root toctree just lists each of these */index.rst files.

When adding a new page to the docs, the first question to ask yourself is: who is this page for? That should tell you which subdirectory to put your page in. You then need to add your page to that subdirectory’s index.rst file.

Within each guide, the docs are broken up by topic. For example, the extending guide has a page for the writing extensions tutorial, a page about testing extensions, a page for the plugins toolkit reference, etc. Again, the topics are ordered with the simplest first and the most advanced last, and reference pages generally at the very end.

The changelog is one page that doesn’t fit into any of the guides, because it’s relevant to all of the different audiences and not only to one particular guide. So the changelog is simply a top-level page on its own. Hopefully we won’t need to add many more of these top-level pages. If you’re thinking about adding a page that serves two or more audiences at once, ask yourself whether you can break that up into separate pages and put each into one of the guides, then link them together usingseealso boxes.

Within a particular page, for example a new page documenting a new feature, our suggestion for what sections the page might have is:

1. **Overview**: a conceptual overview of or introduction to the feature. Explain what the feature provides, why someone might want to use it, and introduce any key concepts users need to understand. This is the why of the feature.
   
   If it’s developer documentation (extension writing, theming, API, or core developer docs), maybe put an architecture guide here.

2. **Tutorials**: tutorials and examples for how to setup the feature, and how to use the feature. This is the how.

3. **Reference**: any reference docs such as config options or API functions.

4. **Troubleshooting**: common error messages and problems, FAQs, how to diagnose problems.

Subdirectories

Some of the guides have subdirectories within them. For example Maintainer’s guide contains a subdirectory Installing CKAN that collects together the various pages about installing CKAN with its own doc/maintaining/installing/index.rst file.
While subdirectories are useful, we recommend that you don’t put further subdirectories inside the subdirectories, try to keep it to at most two levels of subdirectories inside the doc directory. Keep it simple, otherwise the structure becomes confusing, difficult to get an overview of and difficult to navigate.

**Linear ordering**

Keep in mind that Sphinx requires the docs to have a simple, linear ordering. With HTML pages it’s possible to design structure where, for example, someone reads half of a page, then clicks on a link in the middle of the page to go and read another page, then goes back to the middle of the first page and continues reading where they left off. While technically you can do this in Sphinx as well, it isn’t a good idea, things like the navigation links, table of contents, and PDF version will break, users will end up going in circles, and the structure becomes confusing.

So the pages of our Sphinx docs need to have a simple linear ordering - one page follows another, like in a book.

### 7.7.3 Sphinx

This section gives some useful tips about using Sphinx.

**Don’t introduce any new Sphinx warnings**

When you build the docs, Sphinx prints out warnings about any broken cross-references, syntax errors, etc. We aim not to have any of these warnings, so when adding to or editing the docs make sure your changes don’t introduce any new ones.

It’s best to delete the build directory and completely rebuild the docs, to check for any warnings:

```bash
rm -rf build; python setup.py build_sphinx
```

**Maximum line length**

As with Python code, try to limit all lines to a maximum of 79 characters.

**versionadded and versionchanged**

Use Sphinx’s versionadded and versionchanged directives to mark new or changed features. For example:

```plaintext
==============
Tag vocabularies
==============

.. versionadded:: 1.7

CKAN sites can have *tag vocabularies*, which are a way of grouping related tags together into custom fields.

...
```

With versionchanged you usually need to add a sentence explaining what changed (you can also do this with versionadded if you want):
Authorization

.. versionchanged:: 2.0
   Previous versions of CKAN used a different authorization system.

CKAN's authorization system controls which users are allowed to carry out which...

Cross-references and links

Whenever mentioning another page or section in the docs, an external website, a configuration setting, or a class, exception or function, etc. try to cross-reference it. Using proper Sphinx cross-references is better than just typing things like “see above/below” or “see section foo” because Sphinx cross-refs are hyperlinked, and because if the thing you’re referencing to gets moved or deleted Sphinx will update the cross-reference or print a warning.

Cross-referencing to another file

Use :doc: to cross-reference to other files by filename:

See :doc:`configuration`

If the file you’re editing is in a subdir within the doc dir, you may need to use an absolute reference (starting with a /):

See :doc:`/configuration`

See Cross-referencing documents for details.

Cross-referencing a section within a file

Use :ref: to cross-reference to particular sections within the same or another file. First you have to add a label before the section you want to cross-reference to:

```
.. _getting-started:
    Getting started
```

then from elsewhere cross-reference to the section like this:

See :ref:`getting-started`.

see Cross-referencing arbitrary locations.

Cross-referencing to CKAN config settings

Whenever you mention a CKAN config setting, make it link to the docs for that setting in Configuration Options by using :ref: and the name of the config setting:
This works because all CKAN config settings are documented in Configuration Options, and every setting has a Sphinx label that is exactly the same as the name of the setting, for example:

```python
.. _ckan.site_title:

ckan.site_title

Example:

ckan.site_title = Open Data Scotland

Default value: ‘CKAN’

This sets the name of the site, as displayed in the CKAN web interface.

If you add a new config setting to CKAN, make sure to document like this it in Configuration Options.

Cross-referencing to a Python object

Whenever you mention a Python function, method, object, class, exception, etc. cross-reference it using a Sphinx domain object cross-reference. See Referencing other code objects with :py:.

Changing the link text of a cross-reference

With :doc: :ref: and other kinds of link, if you want the link text to be different from the title of the thing you’re referencing, do this:

```python
:doc:`the theming document </theming>`

:ref:`the getting started section <getting-started>`
```

Cross-referencing to an external page

The syntax for linking to external URLs is slightly different from cross-referencing, you have to add a trailing underscore:

```
Link text <http://example.com/>`
```

or to define a URL once and then link to it in multiple places, do:

```
This is `a link`_ and this is `a link`_ and this is `another link <a link>`_.

.. _a link: http://example.com/
```

see Hyperlinks for details.
Substitutions

Substitutions are a useful way to define a value that’s needed in many places (eg. a command, the location of a file, etc.) in one place and then reuse it many times.

You define the value once like this:

```bash
.. |production.ini| replace:: /etc/ckan/default/production.ini
```

and then reuse it like this:

```
Now open your |production.ini| file.
```

|production.ini| will be replaced with the full value /etc/ckan/default/production.ini.

Substitutions can also be useful for achieving consistent spelling and capitalization of names like reStructuredText, PostgreSQL, Nginx, etc.

The `rst_epilog` setting in `doc/conf.py` contains a list of global substitutions that can be used from any file.

Substitutions can’t immediately follow certain characters (with no space in-between) or the substitution won’t work. If this is a problem, you can insert an escaped space, the space won’t show up in the generated output and the substitution will work:

```
pip install -e 'git+\ |git_url|'
```

Similarly, certain characters are not allowed to immediately follow a substitution (without a space) or the substitution won’t work. In this case you can just escape the following characters, the escaped character will show up in the output and the substitution will work:

```
pip install -e 'git+\ |git_url|\#egg=ckan'
```

Also see `Parsed literals` below for using substitutions in code blocks.

Parsed literals

Normally things like links and substitutions don’t work within a literal code block. You can make them work by using a parsed-literal block, for example:

```
.. parsed-literal::

    Copy your development.ini file to create a new production.ini file::

    cp |development.ini| |production.ini|
```

autodoc

We try to use autodoc to pull documentation from source code docstrings into our Sphinx docs, wherever appropriate. This helps to avoid duplicating documentation and also to keep the documentation closer to the code and therefore more likely to be kept up to date.

Whenever you’re writing reference documentation for modules, classes, functions or methods, exceptions, attributes, etc. you should probably be using autodoc. For example, we use autodoc for the Action API reference, the Plugin interfaces reference, etc.

For how to write docstrings, see `Docstrings`.
todo

No new feature (or change to an existing feature) should be missing from the docs. It’s best to document new features or changes as you implement them, but if you really need to merge something without docs then at least add a todo directive to mark where docs need to be added or updated (if it’s a new feature, make a new page or section just to contain the todo):

```
.. todo::
    Add docs for CKAN's builtin social network for data hackers.
```

deprecated

Use Sphinx’s deprecated directive to mark things as deprecated in the docs:

```
.. deprecated:: 3.1
    Use :func:`spam` instead.
```

seealso

Often one page of the docs is related to other pages of the docs or to external pages. A seealso block is a nice way to include a list of related links:

```
.. seealso::

    :doc:`The DataStore extension <datastore>`
    A CKAN extension for storing data.

    CKAN's `demo site <http://demo.ckan.org/>`_
    A demo site running the latest CKAN beta version.
```

Seealso boxes are particularly useful when two pages are related, but don’t belong next to each other in the same section of the docs. For example, we have docs about how to upgrade CKAN, these belong in the maintainer’s guide because they’re for maintainers. We also have docs about how to do a new release, these belong in the contributing guide because they’re for developers. But both sections are about CKAN releases, so we link each to the other using seealso boxes.

7.7.4 Code examples

If you’re going to paste example code into the docs, or add a tutorial about how to do something with code, then:

1. The code should be in standalone Python, HTML, JavaScript etc. files, not pasted directly into the .rst files. You then pull the code into your .rst file using a Sphinx .. literalinclude:: directive (see example below).

2. The code in the standalone files should be a complete working example, with tests. Note that not all of the code from the example needs to appear in the docs, you can include just parts of it using .. literalinclude::, but the example code needs to be complete so it can be tested.
This is so that we don’t end up with a lot of broken, outdated examples and tutorials in the docs because breaking changes have been made to CKAN since the docs were written. If your example code has tests, then when someone makes a change in CKAN that breaks your example those tests will fail, and they’ll know they have to fix their code or update your example.

The plugins tutorial is an example of this technique. ckanext/example_iauthfunctions is a complete and working example extension. The tests for the extension are in ckanext/example_iauthfunctions/tests. Different parts of the reStructuredText file for the tutorial pull in different parts of the example code as needed, like this:

```bash
.. literalinclude :: ../../ckanext/example_iauthfunctions/plugin_v3.py
   :start-after: # We have the logged-in user's user name, get their user id.
   :end-before: # Finally, we can test whether the user is a member of the curators group.
```

literalinclude has a few useful options for pulling out just the part of the code that you want. See the Sphinx docs for literalinclude for details.

You may notice that ckanext/example_iauthfunctions contains multiple versions of the same example plugin, plugin_v1.py, plugin_v2.py, etc. This is because the tutorial walks the user through first making a trivial plugin, and then adding more and more advanced features one by one. Each step of the tutorial needs to have its own complete, standalone example plugin with its own tests.

For more examples, look into the source files for other tutorials in the docs.

### 7.7.5 Style

This section covers things like what tone to use, how to capitalize section titles, etc. Having a consistent style will make the docs nice and easy to read and give them a complete, quality feel.

**Use American spelling**

Use American spellings everywhere: organization, authorization, realize, customize, initialize, color, etc. There’s a list here: https://wiki.ubuntu.com/EnglishTranslation/WordSubstitution

**Spellcheck**

Please spellcheck documentation before merging it into master!

**Commonly used terms**

CKAN Should be written in ALL-CAPS.

email Use email not e-mail.

PostgreSQL, SQLAlchemy, Nginx, Python, SQLite, JavaScript, etc. These should always be capitalized as shown above (including capital first letters for Python and Nginx even when they’re not the first word in a sentence). doc/conf.py defines substitutions for each of these so you don’t have to remember them, see Substitutions.

Web site Two words, with Web always capitalized

frontend Not front-end

command line Two words, not commandline or command-line (this is because we want to be like Neal Stephenson)
CKAN documentation, Release 2.8.5

CKAN config file or configuration file  Not settings file, ini file, etc. Also, the config file contains config options such as ckan.site_id, and each config option is set to a certain setting or value such as ckan.site_id = demo.ckan.org.

Section titles

Capitalization in section titles should follow the same rules as in normal sentences: you capitalize the first word and any proper nouns.

This seems like the easiest way to do consistent capitalization in section titles because it’s a capitalization rule that we all know already (instead of inventing a new one just for section titles).

Right:

• Installing CKAN from package
• Getting started
• Command line interface
• Writing extensions
• Making an API request
• You’re done!
• Libraries available to extensions

Wrong:

• Installing CKAN from Package
• Getting Started
• Command Line Interface
• Writing Extensions
• Making an API Request
• You’re Done!
• Libraries Available To Extensions

For lots of examples of this done right, see Django’s table of contents.

In Sphinx, use the following section title styles:

```
===============
Top-level title
===============

------------------
Second-level title
------------------

Third-level title

Fourth-level title
```

If you need more than four levels of headings, you’re probably doing something wrong, but see: http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html#sections

Chapter 7. Contributing guide
Be conversational

Write in a friendly, conversational and personal tone:

- Use contractions like don’t, doesn’t, it’s etc.
- Use “we”, for example “We’ll publish a call for translations to the ckan-dev and ckan-discuss mailing lists, announcing that the new version is ready to be translated” instead of “A call for translations will be published”.
- Refer to the reader personally as “you”, as if you’re giving verbal instructions to someone in the room: “First, you’ll need to do X. Then, when you’ve done Y, you can start working on Z” (instead of stuff like “First X must be done, and then Y must be done… ”).

Write clearly and concretely, not vaguely and abstractly

Politics and the English Language has some good tips about this, including:

1. Never use a metaphor, simile, or other figure of speech which you are used to seeing in print.
2. Never use a long word where a short one will do.
3. If it’s possible to cut out a word, always cut it out.
4. Never use the passive when you can be active.
5. Never use a foreign phrase, scientific word or jargon word if you can think of an everyday English equivalent.

This will make your meaning clearer and easier to understand, especially for people whose first language isn’t English.

Facilitate skimming

Readers skim technical documentation trying to quickly find what’s important or what they need, so break walls of text up into small, visually identifiable pieces:

- Use lots of inline markup:
  *italics*
  **bold**
  `"code"`

  For code samples or filenames with variable parts, uses Sphinx’s `:samp:` and `:file:` directives.
- Use lists to break up text.
- Use .. note:: and .. warning::, see Sphinx’s paragraph-level markup.
  (reStructuredText actually supports lots more of these: attention, error, tip, important, etc. but most Sphinx themes only style note and warning.)
- Break text into short paragraphs of 5-6 sentences each max.
- Use section and subsection headers to visualize the structure of a page.

7.8 Projects for beginner CKAN developers

The ‘Good for Contribution’ label on Github lists issues which are feasible for people who aren’t intimately familiar with CKAN’s internals. Many of them are things which would be extremely helpful if they got done, but the core team never seems to get around to them. They’re all busy wrestling with the problems that do require familiarity with
the internals. We hope this will make it easier for more people to assist the CKAN project, by giving new developers places to jump in.

These issues vary from simple text changes to more complicated code changes that require more knowledge of Python and CKAN. Do not despair if any individual task seems daunting; there’s probably an easier one. If you have no programming skills, we can still use your help with documentation or translation.

If you wish to take up an issue make sure to keep in touch with the team on the Github issue, the mailing list or IRC.

7.9 CKAN code architecture

This section documents our CKAN-specific coding standards, which are guidelines for writing code that is consistent with the intended design and architecture of CKAN.

7.9.1 Routes

Routes define the connection between CKAN URLs and views that process requests and provide responses.

Default routes are defined in `ckan.config.routing` and extended with the `ckan.plugins.interfaces.IRoutes` plugin interface.

7.9.2 Views

Views process requests by reading and updating data with action function and return a response by rendering Jinja2 templates. CKAN views are defined in `ckan.controllers` and templates in `ckan.templates`. 
Views and templates may use `logic.check_access` or `ckan.lib.helpers.check_access()` to hide links or render helpful errors but action functions, not views, are responsible for actually enforcing permissions checking.

Plugins define new views by adding or updating routes. For adding templates or helper functions from a plugin see the Theming guide and Adding your own template helper functions.

**Template helper functions**

Template helper functions are used for code that is reused frequently or code that is too complicated to be included in the templates themselves.

Template helpers should never perform expensive queries or update data.

`ckan.lib.helpers` contains helper functions that can be used from `ckan.controllers` or from templates. When developing for ckan core, only use the helper functions found in `ckan.lib.helpers._allowed_functions_`.

**Always go through the action functions**

Whenever some code, for example in `ckan.lib` or `ckan.controllers`, wants to get, create, update or delete an object from CKAN’s model it should do so by calling a function from the `ckan.logic.action` package, and not by accessing `ckan.model` directly.

**Use `get_action()`**

Don’t call `logic.action` functions directly, instead use `get_action()`. This allows plugins to override action functions using the IActions plugin interface. For example:

```python
ckan.logic.get_action('group_activity_list')(...)  
```

Instead of

```python
ckan.logic.action.get.group_activity_list(...)  
```

Views and templates may check authorization to avoid rendering.

**Don’t pass ORM objects to templates**

Don’t pass SQLAlchemy ORM objects (e.g. `ckan.model.User` objects) to templates (for example by adding them to `c`, passing them to `render()` in the `extra_vars` dict, returning them from template helper functions, etc.)

Using ORM objects in the templates often creates SQLAlchemy “detached instance” errors that cause 500 Server Errors and can be difficult to debug.

### 7.9.3 Logic

Logic includes action functions, auth functions, background tasks and business logic.

Action functions have a uniform interface accepting a dictionary of simple strings lists, dictionaries or files (wrapped in a `cgi.FieldStorage` objects). They return simple dictionaries or raise one of a small number of exceptions including `ckan.logic.NotAuthorized`, `ckan.logic.NotFound` and `ckan.logic.ValidationError`.
Plugins override action functions with the `ckan.plugins.interfaces.IActions` interface and auth functions with the `ckan.plugins.interfaces.IAuthFunctions` interface.

**Action functions are exposed in the API**

The functions in `ckan.logic.action` are exposed to the world as the *API guide*. The API URL for an action function is automatically generated from the function name, for example `ckan.logic.action.create.package_create()` is exposed at `/api/action/package_create`. See Steve Yegge’s Google platforms rant for some interesting discussion about APIs.

All publicly visible functions in the `ckan.logic.action.{create,delete,get,update}` namespaces will be exposed through the *API guide*. **This includes functions imported** by those modules, **as well as any helper functions** defined within those modules. To prevent inadvertent exposure of non-action functions through the action api, care should be taken to:

1. **Import modules correctly** (see *Imports*). For example:

   ```python
   import ckan.lib.search as search
   search.query_for(...)  
   ```

2. **Hide any locally defined helper functions**:

   ```python
   def _a_useful_helper_function(x, y, z):
       '''This function is not exposed because it is marked as private''
       return x+y+z
   ```

3. **Bring imported convenience functions into the module namespace as private members**:

   ```python
   _get_or_bust = logic.get_or_bust
   ```

**Auth functions and check_access()**

Each action function defined in `ckan.logic.action` should use its own corresponding auth function defined in `ckan.logic.auth`. Instead of calling its auth function directly, an action function should go through `ckan.logic.check_access` (which is aliased `_check_access` in the action modules) because this allows plugins to override auth functions using the `IAuthFunctions` plugin interface. For example:

```python
def package_show(context, data_dict):
    _check_access('package_show', context, data_dict)
```

`check_access` will raise an exception if the user is not authorized, which the action function should not catch. When this happens the user will be shown an authorization error in their browser (or will receive one in their response from the API).

**logic.get_or_bust()**

The `data_dict` parameter of logic action functions may be user provided, so required files may be invalid or absent. Naive Code like:

```python
id = data_dict['id']  
```

may raise a `KeyError` and cause CKAN to crash with a 500 Server Error and no message to explain what went wrong. Instead do:
id = _get_or_bust(data_dict, "id")

which will raise ValidationError if "id" is not in data_dict. The ValidationError will be caught and the user will get a 400 Bad Request response and an error message explaining the problem.

Validation and ckan.logic.schema

Logic action functions can use schema defined in ckan.logic.schema to validate the contents of the data_dict parameters that users pass to them.

An action function should first check for a custom schema provided in the context, and failing that should retrieve its default schema directly, and then call _validate() to validate and convert the data. For example, here is the validation code from the user_create() action function:

```python
schema = context.get('schema') or ckan.logic.schema.default_user_schema()
session = context['session']
validated_data_dict, errors = _validate(data_dict, schema, context)
if errors:
    session.rollback()
    raise ValidationError(errors)
```

7.9.4 Models

Ideally SQLAlchemy should only be used within ckan.model and not from other packages such as ckan.logic. For example instead of using an SQLAlchemy query from the logic package to retrieve a particular user from the database, we add a get() method to ckan.model.user.User:

```python
@classmethod
def get(cls, user_id):
    query = ...
    ...
    return query.first()
```

Now we can call this method from the logic package.

7.9.5 Deprecation

• Anything that may be used by extensions, themes or API clients needs to maintain backward compatibility at call-site. For example: action functions, template helper functions and functions defined in the plugins toolkit.

• The length of time of deprecation is evaluated on a function-by-function basis. At minimum, a function should be marked as deprecated during a point release.

• To deprecate a function use the ckan.lib.maintain.deprecated() decorator and add “deprecated” to the function’s docstring:

```python
@maintain.deprecated("helpers.get_action() is deprecated and will be removed "
                     "in a future version of CKAN. Instead, please use the 
                     "extra_vars param to render() in your controller to pass 
                     "results from action functions to your templates.")
def get_action(action_name, data_dict=None):
```

(continues on next page)
'''Calls an action function from a template. Deprecated in CKAN 2.3.'''

```python
if data_dict is None:
    data_dict = {}
return logic.get_action(action_name)({}, data_dict)
```

- Any deprecated functions should be added to an API changes and deprecations section in the Changelog entry for the next release (do this before merging the deprecation into master)

- Keep the deprecation messages passed to the decorator short, they appear in logs. Put longer explanations of why something was deprecated in the changelog.

## 7.10 CSS coding standards

**Note:** For CKAN 2.0 we use LESS as a pre-processor for our core CSS. View Front-end Documentation for more information on this subject.

### 7.10.1 Formatting

All CSS documents must use **two spaces** for indentation and files should have no trailing whitespace. Other formatting rules:

- Use soft-tabs with a two space indent.
- Use double quotes.
- Use shorthand notation where possible.
- Put spaces after : in property declarations.
- Put spaces before { in rule declarations.
- Use hex color codes #000 unless using rgba().
- Always provide fallback properties for older browsers.
- Use one line per property declaration.
- Always follow a rule with one line of whitespace.
- Always quote url() and @import() contents.
- Do not indent blocks.

For example:

```css
.media {
    overflow: hidden;
    color: #fff;
    background-color: #000; /* Fallback value */
    background-image: linear-gradient(black, grey);
}

.media .img {
    float: left;
    border: 1px solid #ccc;
}
```
7.10.2 Naming

All ids, classes and attributes must be lowercase with hyphens used for separation.

/* GOOD */
.dataset-list {}

/* BAD */
.datasetlist {}
.datasetList {}
.dataset_list {}

7.10.3 Comments

Comments should be used liberally to explain anything that may be unclear at first glance, especially IE workarounds or hacks.

.prose p {
  font-size: 1.1666em /* 14px / 12px */;
}

.ie7 .search-form {
  /*
   Force the item to have layout in IE7 by setting display to block.
   See: http://reference.sitepoint.com/css/haslayout
  */
  display: inline-block;
}

7.10.4 Modularity and specificity

Try keep all selectors loosely grouped into modules where possible and avoid having too many selectors in one declaration to make them easy to override.

/* Avoid */
ul#dataset-list {}
ul#dataset-list li {}
ul#dataset-list li p a.download {}

Instead here we would create a dataset “module” and styling the item outside of the container allows you to use it on it’s own e.g. on a dataset page:
In the same vein use classes make the styles more robust, especially where the HTML may change. For example when styling social links:

```html
<ul class="social">
  <li><a href">Twitter</a></li>
  <li><a href">Facebook</a></li>
  <li><a href">LinkedIn</a></li>
</ul>
```

You may use pseudo selectors to keep the HTML clean:

```css
.social li:nth-child(1) a {
  background-image: url(twitter.png);
}
.social li:nth-child(2) a {
  background-image: url(facebook.png);
}
.social li:nth-child(3) a {
  background-image: url(linked-in.png);
}
```

However this will break any time the HTML changes for example if an item is added or removed. Instead we can use class names to ensure the icons always match the elements (Also you’d probably sprite the image :).

```css
.social .twitter {
  background-image: url(twitter.png);
}
.social .facebook {
  background-image: url(facebook.png);
}
.social .linked-in {
  background-image: url(linked-in.png);
}
```

Avoid using tag names in selectors as this prevents re-use in other contexts.

```css
/* Cannot use this class on an <ol> or <div> element */
ul.dataset-item {}
```

Also ids should not be used in selectors as it makes it far too difficult to override later in the cascade.

```css
/* Cannot override this button style without including an id */
.btn#download {}
```

### 7.11 HTML coding standards

See also:
String internationalization  How to mark strings for translation.

7.11.1 Formatting

All HTML documents must use two spaces for indentation and there should be no trailing whitespace. HTML5 syntax must be used and all attributes must use double quotes around attributes.

```
<video autoplay="autoplay" poster="poster_image.jpg">
  <source src="foo.ogg" type="video/ogg">
</video>
```

HTML5 elements should be used where appropriate reserving `<div>` and `<span>` elements for situations where there is no semantic value (such as wrapping elements to provide styling hooks).

7.11.2 Doctype and layout

All documents must be using the HTML5 doctype and the `<html>` element should have a "lang" attribute. The `<head>` should also at a minimum include "viewport" and "charset" meta tags.

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <meta charset="utf-8" />  
    <meta name="viewport" content="width=device-width, initial-scale=1"> 
    <title>Example Site</title> 
  </head>
  <body></body>
</html>
```

7.11.3 Forms

Form fields must always include a `<label>` element with a "for" attribute matching the "id" on the input. This helps accessibility by focusing the input when the label is clicked, it also helps screen readers match labels to their respective inputs.

```
<label for="field-email">email</label>
<input type="email" id="field-email" name="email" value="" />
```

Each `<input>` should have an "id" that is unique to the page. It does not have to match the "name" attribute.

Forms should take advantage of the new HTML5 input types where they make sense to do so, placeholder attributes should also be included where relevant. Including these can provided enhancements in browsers that support them such as tailored inputs and keyboards.

```
<div>
  <label for="field-email">Email</label>
  <input type="email" id="field-email" name="email" value="name@example.com" />
</div>
<div>
  <label for="field-phone">Phone</label>
  <input type="phone" id="field-phone" name="phone" value="" placeholder="+44 077 12345 678" />
</div>
```

(continues on next page)
Wufoo provides an excellent reference for these attributes.

### 7.11.4 Including meta data

Classes should ideally only be used as styling hooks. If you need to include additional data in the HTML document, for example to pass data to JavaScript, then the HTML5 `data-` attributes should be used.

```html
<a class="btn" data-format="csv">Download CSV</a>
```

These can then be accessed easily via jQuery using the `.data()` method.

```javascript
jQuery('.btn').data('format'); //=> "csv"
```

// Get the contents of all data attributes.
```javascript
jQuery('.btn').data(); => {format: "csv"}
```

One thing to note is that the JavaScript API for datasets will convert all attribute names into camelCase. So "data-file-format" will become `fileFormat`.

For example:

```html
<a class="btn" data-file-format="csv">Download CSV</a>
```

Will become:

```javascript
jQuery('.btn').data('fileFormat'); //=> "csv"
jQuery('.btn').data(); => {fileFormat: "csv"}
```

Ideally you should be using CKAN's JavaScript module format for defining how JavaScript is initiated and interacts with the DOM.

### 7.11.5 Targeting Internet Explorer

Targeting lower versions of Internet Explorer (IE), those below version 9, should be handled by the stylesheets. Small fixes should be provided inline using the .ie specific class names. Larger fixes may require a separate stylesheet but try to avoid this if at all possible.

Adding IE specific classes:

```html
<!DOCTYPE html>
<!--[if lt IE 7]><html lang="en" class="ie ie6"> <![endif]-->
<!--[if IE 7]><html lang="en" class="ie ie7"> <![endif]-->
<!--[if IE 8]><html lang="en" class="ie ie8"> <![endif]-->
<!--[if gt IE 8]><![endif]--><html lang="en" <!--><![endif]-->
```

**Note:** Only add lines for classes that are actually being used.
These can then be used within the CSS:

```css
.clear:before, .clear:after {
  content: "";
  display: table;
}
.clear:after {
  clear: both;
}
.ie7 .clear {
  zoom: 1; /* For IE 6/7 (trigger hasLayout) */
}
```

### 7.11.6 i18n

Don’t include line breaks within `<p>` blocks. ie do this:

```html
<p>Blah foo blah</p>  
<p>New paragraph, blah</p>
```

And **not**:

```html
<p>Blah foo blah  
    New paragraph, blah</p>
```

### 7.12 JavaScript coding standards

**See also:**

*String internationalization*  How to mark strings for translation.

#### 7.12.1 Formatting

All JavaScript documents must use **two spaces** for indentation. This is contrary to the *OKFN Coding Standards* but matches what’s in use in the current code base.

Coding style must follow the *idiomatic.js* style but with the following exceptions.

**Note:**  Idiomatic is heavily based upon Douglas Crockford’s style guide which is recommended by the *OKFN Coding Standards*.

**White space**

Two spaces must be used for indentation at all times. Unlike in idiomatic whitespace must not be used _inside_ parentheses between the parentheses and their Contents.
function getUrl(full) {
    var url = '/styleguide/javascript/';
    if (full) {
        url = 'http://okfn.github.com/ckan' + url;
    }
    return url;
}

// GOOD:
function getUrl(full) {
    var url = '/styleguide/javascript/';
    if (full) {
        url = 'http://okfn.github.com/ckan' + url;
    }
    return url;
}

**Note:** See section 2.D.1.1 of idiomatic for more examples of this syntax.

**Quotes**

Single quotes should be used everywhere unless writing JSON or the string contains them. This makes it easier to create strings containing HTML.

```javascript
jQuery('<div id="my-div" />' ).appendTo('body');
```

Object properties need not be quoted unless required by the interpreter.

```javascript
var object = {
    name: 'bill',
    'class': 'user-name'
};
```

**Variable declarations**

One `var` statement must be used per variable assignment. These must be declared at the top of the function in which they are being used.

```javascript
// GOOD:
var good = 'string';
var alsoGood = 'another';

// GOOD:
var good = 'string';
var okay = [
    'hmm', 'a bit', 'better'
];

// BAD:
var good = 'string',
    iffy = [
```
Declare variables at the top of the function in which they are first used. This avoids issues with variable hoisting. If a variable is not assigned a value until later in the function then it is okay to define more than one per statement.

```javascript
// BAD: contrived example.
function lowercaseNames(names) {
    var names = [];

    for (var index = 0, length = names.length; index < length; index += 1) {
        var name = names[index];
        names.push(name.toLowerCase());
    }

    var sorted = names.sort();
    return sorted;
}

// GOOD:
function lowercaseNames(names) {
    var names = [];
    var index, sorted, name;

    for (index = 0, length = names.length; index < length; index += 1) {
        name = names[index];
        names.push(name.toLowerCase());
    }

    sorted = names.sort();
    return sorted;
}
```

### 7.12.2 Naming

All properties, functions and methods must use lowercase camelCase:

```javascript
var myUsername = 'bill';
var methods = {
    getSomething: function () {} {}
};
```

Constructor functions must use uppercase CamelCase:

```javascript
function DatasetSearchView() {}
```

Constants must be uppercase with spaces delimited by underscores:

```javascript
var env = {
    PRODUCTION: 'production',
    DEVELOPMENT: 'development',
    TESTING: 'testing'
};
```

Event handlers and callback functions should be prefixed with “on”:

```javascript
```
function onDownloadClick(event) {} 
jQuery('.download').click(onDownloadClick);

Boolean variables or methods returning boolean functions should prefix the variable name with “is”:

function isAdmin() {} 
var canEdit = isUser() && isAdmin();

**Note:** Alternatives are “has”, “can” and “should” if they make more sense

Private methods should be prefixed with an underscore:

View.extend({
  "click": "_onClick",
  _onClick: function (event) {
  }
});

Functions should be declared as named functions rather than assigning an anonymous function to a variable.

// GOOD: 
function getName() {
}
// BAD: 
var getName = function () {
};

Named functions are generally easier to debug as they appear named in the debugger.

### 7.12.3 Comments

Comments should be used to explain anything that may be unclear when you return to it in six months time. Single line comments should be used for all inline comments that do not form part of the documentation.

```javascript
// Export the function to either the exports or global object depending
// on the current environment. This can be either an AMD module, CommonJS
// module or a browser.
if (typeof module.define === 'function' && module.define.amd) {
  module.define('broadcast', function () {
    return Broadcast;
  });
} else if (module.exports) {
  module.exports = Broadcast;
} else {
  module.Broadcast = Broadcast;
}
```
7.12.4 JSHint

All JavaScript should pass JSHint before being committed. This can be installed using npm (which is bundled with node) by running:

```
$ npm -g install jshint
```

Each project should include a jshint.json file with appropriate configuration options for the tool. Most text editors can also be configured to read from this file.

7.12.5 Documentation

For documentation we use a simple markup format to document all methods. The documentation should provide enough information to show the reader what the method does, arguments it accepts and a general example of usage. Also for API’s and third party libraries, providing links to external documentation is encouraged.

The formatting is as follows:

```javascript
/* My method description. Should describe what the method does and where it should be used.
 * param1 - The method params, one per line (default: null)
 * param2 - A default can be provided in brackets at the end.
 * Example
 * // Indented two spaces. Should give a common example of use.
 * client.getTemplate('index.html', {limit: 1}, function (html) {
 *    module.el.html(html);
 * });
 * Returns describes what the object returns.
 */
```

For example:

```javascript
/* Loads an HTML template from the CKAN snippet API endpoint. Template variables can be passed through the API using the params object.
 * Optional success and error callbacks can be provided or these can be attached using the returns jQuery promise object.
 * filename - The filename of the template to load.
 * params - An optional object containing key/value arguments to be passed into the template.
 * success - An optional success callback to be called on load. This will recieve the HTML string as the first argument.
 * error - An optional error callback to be called if the request fails.
 * Example
 * client.getTemplate('index.html', {limit: 1}, function (html) {
 *    module.el.html(html);
 * });
 * Returns a jqXHR promise object that can be used to attach callbacks.
 */
```
7.12.6 Testing

For unit testing we use the following libraries.

- **Mocha**: As a BDD unit testing framework.
- **Sinon**: Provides spies, stubs and mocks for methods and functions.
- **Chai**: Provides common assertions.

Tests are run from the test/index.html directory. We use the BDD interface (describe(), it() etc.) provided by mocha and the assert interface provided by chai.

Generally we try and have the core functionality of all libraries and modules unit tested.

7.12.7 Best practices

Forms

All forms should work without JavaScript enabled. This means that they must submit application/x-www-form-urlencoded data to the server and receive an appropriate response. The server should check for the X-Requested-With: XMLHttpRequest header to determine if the request is an ajax one. If so it can return an appropriate format, otherwise it should issue a 303 redirect.

The one exception to this rule is if a form or button is injected with JavaScript after the page has loaded. It’s then not part of the HTML document and can submit any data format it pleases.

Ajax

**Note**: Calls to the CKAN API from JavaScript should be done through the CKAN client.

Ajax requests can be used to improve the experience of submitting forms and other actions that require server interactions. Nearly all requests will go through the following states.

1. User clicks button.
2. JavaScript intercepts the click and disables the button (add disabled attr).
3. A loading indicator is displayed (add class .loading to button).
4. The request is made to the server.
5. (a) On success the interface is updated.
   (b) On error a message is displayed to the user if there is no other way to resolve the issue.
6. The loading indicator is removed.
7. The button is re-enabled.

Here’s a possible example for submitting a search form using jQuery.

```javascript
jQuery('#search-form').submit(function (event) {
    var form = $(this);
    var button = $('[type=submit]', form);

    // Prevent the browser submitting the form.
    event.preventDefault();
}
```
button.prop('disabled', true).addClass('loading');

jQuery.ajax({
    type: this.method,
    data: form.serialize(),
    success: function (results) {
        updatePageWithResults(results);
    },
    error: function () {
        showSearchError('Sorry we were unable to complete this search');
    },
    complete: function () {
        button.prop('disabled', false).removeClass('loading');
    }
});

This covers possible issues that might arise from submitting the form as well as providing the user with adequate feedback that the page is doing something. Disabling the button prevents the form being submitted twice and the error feedback should hopefully offer a solution for the error that occurred.

**Event handlers**

When using event handlers to listen for browser events it’s a common requirement to want to cancel the default browser action. This should be done by calling the `event.preventDefault()` method:

```javascript
jQuery('button').click(function (event) {
    event.preventDefault();
});
```

It is also possible to return `false` from the callback function. Avoid doing this as it also calls the `event.stopPropagation()` method which prevents the event from bubbling up the DOM tree. This prevents other handlers listening for the same event. For example an analytics click handler attached to the `<body>` element.

Also jQuery (1.7+) now provides the `.on()` and `.off()` methods as alternatives to `.bind()`, `.unbind()`, `.delegate()` and `.undelegate()` and they should be preferred for all tasks.

** Templating**

Small templates that will not require customisation by the instance can be placed inline. If you need to create multi-line templates use an array rather than escaping newlines within a string:

```javascript
var template = [
    '<li>',
    '<span>',
    '</li>',
].join('');
```

Always **localise text strings** within your template. If you are including them inline this can be done with jQuery:

```javascript
jQuery(template).find('span').text(_.trans('This is my text string'));
```

Larger templates can be loaded in using the CKAN snippet API. Modules get access to this functionality via the `sandbox.client` object:

7.12. JavaScript coding standards 359
initialize: function () {
    var el = this.el;
    this.sandbox.client.getTemplate('dataset.html', function (html) {
        el.html(html);
    });
}

The primary benefits of this is that the localisation can be done by the server and it keeps the JavaScript modules free from large strings.

### 7.13 Python coding standards

For Python code style follow PEP 8 plus the guidelines below.

Some good links about Python code style:

- Guide to Python from Hitchhiker’s
- Google Python Style Guide

See also:

**String internationalization** How to mark strings for translation.

#### 7.13.1 Use single quotes

Use single-quotes for string literals, e.g. ‘my-identifier’, *but* use double-quotes for strings that are likely to contain single-quote characters as part of the string itself (such as error messages, or any strings containing natural language), e.g. "You've got an error!".

Single-quotes are easier to read and to type, but if a string contains single-quote characters then double-quotes are better than escaping the single-quote characters or wrapping the string in double single-quotes.

We also use triple single-quotes for docstrings, see *Docstrings*.

#### 7.13.2 Imports

- Avoid creating circular imports by only importing modules more specialized than the one you are editing.

CKAN often uses code imported into a data structure instead of importing names directly. For example CKAN controllers only use `get_action` to access logic functions. This allows customization by CKAN plugins.
• Don’t use `from module import *`. Instead list the names you need explicitly:

```python
from module import name1, name2
```

Use parenthesis around the names if they are longer than one line:

```python
from module import (name1, name2, ...
    name12, name13)
```

Most of the current CKAN code base imports just the modules and then accesses names with `module.name`. This allows circular imports in some cases and may still be necessary for exiting code, but is not recommended for new code.

• Make all imports at the start of the file, after the module docstring. Imports should be grouped in the following order:
  1. Standard library imports
  2. Third-party imports
  3. CKAN imports

### 7.13.3 Logging

We use the Python standard library’s `logging module` to log messages in CKAN, e.g.:  

7.13. Python coding standards
import logging
...
logger = logging.getLogger(__name__)
...
logger.debug('some debug message')

When logging:

- Keep log messages short.
- Don’t include object representations in the log message. It is useful to include a domain model identifier where appropriate.
- Choose an appropriate log-level (DEBUG, INFO, ERROR, WARNING or CRITICAL, see Python’s Logging HOWTO).

### 7.13.4 String formatting

Don’t use the old %s style string formatting, e.g. "i am a %s" % sub. This kind of string formatting is not helpful for internationalization.

Use the new .format() method instead, and give meaningful names to each replacement field, for example:

```python
_(' ... {foo} ... {bar} ...').format(foo='foo-value', bar='bar-value')
```

### 7.13.5 Unicode handling

CKAN strives to only use Unicode internally (via the unicode type) and to convert to/from ASCII at the interface to other systems and libraries if necessary.

See also:

- *Unicode handling*  Details on Unicode handling in CKAN

### 7.13.6 Docstrings

We want CKAN’s docstrings to be clear and easy to read for programmers who are smart and competent but who may not know a lot of CKAN technical jargon and whose first language may not be English. We also want it to be easy to maintain the docstrings and keep them up to date with the actual behaviour of the code as it changes over time. So:

- All modules and all public functions, classes and methods exported by a module should normally have docstrings (see PEP 257).
- Keep docstrings short, describe only what’s necessary and no more.
- Keep docstrings simple: use plain, concise English.
- Try to avoid repetition.

**PEP 257 (Docstring Conventions)**

Generally, follow PEP 257 for docstrings. We’ll only describe the ways that CKAN differs from or extends PEP 257 below.

CKAN docstrings deviate from PEP 257 in a couple of ways:
• We use '''triple single quotes''' around docstrings, not """"triple double quotes"""
   (put triple single quotes around one-line docstrings as well as multi-line ones, it makes them easier to expand
   later)
• We use Sphinx domain object cross-references to cross-reference to other code objects (see below)
• We use Sphinx directives for documenting parameters, exceptions and return values (see below)

7.13.7 Referencing other code objects with :py:

If you want to refer to another Python or JavaScript module, function or class etc. in a docstring (or from a .rst file),
use Sphinx domain object cross-references, for example:

```plaintext
```

For the full list of types of cross-reference, see the Sphinx docs.

**Note:** These kinds of cross-references can also be used to reference other types of object besides Python objects, for
example JavaScript objects or even command-line scripts and options and environment variables. See the Sphinx docs
for the full details.

Cross-referencing objects like this means that Sphinx will style the reference with the right CSS, and hyperlink the
reference to the docs for the referenced object. Sphinx can also generate error messages when non-existent objects are
referenced, which helps to keep the docs up to date as the code changes.

**Tip:** Sphinx will render a cross-reference like :py:func:`ckan.logic.action.create.package_create` as the full name of the function: `ckan.logic.action.create.package_create()`.
If you want the docs to contain only the local name of the function (e.g. just `package_create()`), put a ~ at the start:

```plaintext
~ckan.logic.action.create.package_create
```

(But you should always use the fully qualified name in your docstring or *.rst file.)

**Documenting exceptions raised with :raises**

There are a few guidelines that CKAN code should follow regarding exceptions:

1. **All public functions that CKAN exports for third-party code to use should document any exceptions they raise.** See below for how to document exceptions raised.

   For example the template helper functions in `ckan.lib.helpers`, anything imported into `ckan.plugins.toolkit`, and all of the action API functions defined in `ckan.logic.action`, should list exceptions raised in their docstrings.

   This is because CKAN themes, extensions and API clients need to be able to call CKAN code without crashing,
   so they need to know what exceptions they should handle (and extension developers shouldn’t have to understand
   the CKAN core source code).
2. On the other hand, **internal functions that are only used within CKAN shouldn’t list exceptions in their docstrings.**

   This is because it would be difficult to keep all the exception lists up to date with the actual code behaviour, so the docstrings would become more misleading than useful.

3. **Code should only raise exceptions from within its allowed set.**

   Each module in CKAN has a set of zero or more exceptions, defined somewhere near the module, that code in that module is allowed to raise. For example `ckan/logic/__init__.py` defines a number of exception types for code in `ckan/logic/` to use. CKAN code should never raise exceptions types defined elsewhere in CKAN, in third-party code or in the Python standard library.

4. **All code should catch any exceptions raised by called functions,** and either handle the exception, re-raise the exception (if it’s from the code’s set of allowed exception types), or wrap the exception in an allowed exception type and re-raise it.

   This is to make it easy for a CKAN core developer to look at the source code of an internal function, scan it for the keyword `raise`, and see what types of exception the function may raise, so they know what exceptions they need to catch if they’re going to call the function. Developers shouldn’t have to read the source of all the functions that a function calls (and the functions they call...) to find out what exceptions they needs to catch to call a function without crashing.

**Todo:** Insert examples of how to re-raise and how to wrap-and-re-raise an exception.

Use `:raises:` to document exceptions raised by public functions. The docstring should say what type of exception is raised and under what conditions. Use `:py:class:` to reference exception types. For example:

```python
def member_list(context, data_dict=None):
    '''Return the members of a group.

    ... (parameters and return values documented here) ...

    :raises: :py:class:`ckan.logic.NotFound`: if the group doesn't exist
    ...
```

**Sphinx field lists**

Use Sphinx field lists for documenting the parameters, exceptions and returns of functions:

- Use `:param` and `:type` to describe each parameter
- Use `:returns` and `:rtype` to describe each return
- Use `:raises` to describe each exception raised

Example of a short docstring:

```python
@property
def packages(self):
    '''Return a list of all packages that have this tag, sorted by name.

    :rtype: list of ckan.model.package.Package objects
    ...
```

Example of a longer docstring:
@classmethod
def search_by_name(cls, search_term, vocab_id_or_name=None):

    '''Return all tags whose names contain a given string.

    By default only free tags (tags which do not belong to any vocabulary) are returned. If the optional argument `vocab_id_or_name` is given then only tags from that vocabulary are returned.

    :param search_term: the string to search for in the tag names
    :type search_term: string
    :param vocab_id_or_name: the id or name of the vocabulary to look in
        (optional, default: None)
    :type vocab_id_or_name: string

    :returns: a list of tags that match the search term
    :rtype: list of ckan.model.tag.Tag objects
    ...

The phrases that follow :param foo:, :type foo:, or :returns: should not start with capital letters or end with full stops. These should be short phrases and not full sentences. If more detail is required put it in the function description instead.

Indicate optional arguments by ending their descriptions with (optional) in brackets. Where relevant also indicate the default value: (optional, default: 5).

You can also use a little inline reStructuredText markup in docstrings, e.g. *stars for emphasis* or `double-backticks for literal text`.

**Action API docstrings**

Docstrings from CKAN’s action API are processed with autodoc and included in the API chapter of CKAN’s documentation. The intended audience of these docstrings is users of the CKAN API and not (just) CKAN core developers.

In the Python source each API function has the same two arguments (context and data_dict), but the docstrings should document the keys that the functions read from data_dict and not context and data_dict themselves, as this is what the user has to POST in the JSON dict when calling the API.

Where practical, it’s helpful to give examples of param and return values in API docstrings.

CKAN datasets used to be called packages and the old name still appears in the source, e.g. in function names like package_list(). When documenting functions like this write dataset not package, but the first time you do this put package after it in brackets to avoid any confusion, e.g.

```python
def package_show(context, data_dict):
    '''Return the metadata of a dataset (package) and its resources.
```

Example of a ckan.logic.action API docstring:

```python
def vocabulary_create(context, data_dict):
    '''Create a new tag vocabulary.

    You must be a sysadmin to create vocabularies.

    :param name: the name of the new vocabulary, e.g. `'Genre'`
    :type name: string
    :param tags: the new tags to add to the new vocabulary, for the format of
```
7.13.8 Some helpful tools for Python code quality

There are various tools that can help you to check your Python code for PEP8 conformance and general code quality. We recommend using them.

- **pep8** checks your Python code against some of the style conventions in PEP 8. As mentioned above, only perform style clean-ups on master to help avoid spurious merge conflicts.
- **pylint** analyzes Python source code looking for bugs and signs of poor quality.
- **pyflakes** also analyzes Python programs to detect errors.
- **flake8** combines both pep8 and pyflakes into a single tool.
- **Syntastic** is a Vim plugin with support for flake8, pyflakes and pylint.

7.14 String internationalization

All user-facing Strings in CKAN Python, JavaScript and Jinja2 code should be internationalized, so that our translators can then localize the strings for each of the many languages that CKAN supports. This guide shows CKAN developers how to internationalize strings, and what to look for regarding string internationalization when reviewing a pull request.

---

**Note:** *Internationalization* (or i18n) is the process of marking strings for translation, so that the strings can be extracted from the source code and given to translators. *Localization* (l10n) is the process of translating the marked strings into different languages.

**See also:**

- **Translating CKAN** If you want to translate CKAN, this page documents the process that translators follow to localize CKAN into different languages.
- **Doing a CKAN release** The processes for extracting internationalized strings from CKAN and uploading them to Transifex to be translated, and for downloading the translations from Transifex and loading them into CKAN to be displayed are documented on this page.

---

**Note:** Much of the existing code in CKAN was written before we had these guidelines, so it doesn’t always do things as described on this page. When writing new code you should follow the guidelines on this page, not the existing code.

7.14.1 Internationalizing strings in Jinja2 templates

Most user-visible strings should be in the Jinja2 templates, rather than in Python or JavaScript code. This doesn’t really matter to translators, but it’s good for the code to separate logic and content. Of course this isn’t always possible. For example when error messages are delivered through the API, there’s no Jinja2 template involved.
The preferred way to internationalize strings in Jinja2 templates is by using the trans tag from Jinja2’s i18n extension, which is available to all CKAN core and extension templates and snippets.

Most of the following examples are taken from the Jinja2 docs.

To internationalize a string put it inside a {%- trans %} tag:

```
<p>{%- trans %}This paragraph is translatable.{%- endtrans %}</p>
```

You can also use variables from the template’s namespace inside a {%- trans %}:

```
<p>{%- trans %}Hello {{ user }}!{%- endtrans %}</p>
```

(Only variable tags are allowed inside trans tags, not statements.)

You can pass one or more arguments to the {%- trans %} tag to bind variable names for use within the tag:

```
<p>{%- trans user=user.username %}Hello {{ user }}!{%- endtrans %}</p>

{% trans book_title=book.title, author=author.name %}
This is {{ book_title }} by {{ author }}
{% endtrans %}
```

To handle different singular and plural forms of a string, use a {%- pluralize %} tag:

```
{% trans count=list|length %}
There is {{ count }} {{ name }} object.
{% pluralize %}
There are {{ count }} {{ name }} objects.
{% endtrans %}
```

(In English the first string will be rendered if count is 1, the second otherwise. For other languages translators will be able to provide their own strings for different values of count.)

The first variable in the block (count in the example above) is used to determine which of the singular or plural forms to use. Alternatively you can explicitly specify which variable to use:

```
{% trans ..., user_count=users|length %}
...
{% pluralize user_count %}
...
{% endtrans %}
```

The {%- trans %} tag is preferable, but if you need to pluralize a string within a Jinja2 expression you can use the _() and ungettext() functions:

```
{% set hello = _('Hello World!') %}
```

To use variables in strings, use Python format string syntax and then call the .format() method on the string that _() returns:

```
{% set hello = _('Hello {name}!).format(name=user.name) %}
```

Singular and plural forms are handled by ungettext():

```
{% set text = ungettext(  
    '{num} apple', '{num} apples', num_apples).format(num=num_apples) %}
```
Note: There are also gettext() and ngettext() functions available to templates, but we recommend using _() and ungettext() for consistency with CKAN’s Python code. This deviates from the Jinja2 docs, which do use gettext() and ngettext().

_() is not an alias for gettext() in CKAN’s Jinja2 templates, _() is the function provided by Pylons, whereas gettext() is the version provided by Jinja2, their behaviors are not exactly the same.

7.14.2 Internationalizing strings in Python code

CKAN uses the _() and ngettext() functions from the Flask-Babel library to internationalize strings in Python code.

Note: Code running on Pylons will use the functions provided by the pylons.i18n.translation module, but their behaviour is the same.

Core CKAN modules should import _() and ungettext() from ckan.common, i.e. from ckan.common import _, ungettext (don’t import flask_babel._() or pylons.i18n.translation._() directly, for example).

CKAN plugins should import ckan.plugins.toolkit and use ckan.plugins.toolkit._() and ckan.plugins.toolkit.ungettext(), i.e. do import ckan.plugins.toolkit as toolkit and then use toolkit._() and toolkit.ungettext() (see Plugins toolkit reference).

To internationalize a string pass it to the _() function:

```python
my_string = _("This paragraph is translatable.")
```

To use variables in a string, call the .format() method on the translated string that _() returns:

```python
hello = _("Hello {user}!").format(user=user.name)

book_description = _("This is { book_title } by { author }").format(
    book_title=book.title, author=author.name)
```

To handle different plural and singular forms of a string, use ungettext():

```python
translated_string = ungettext(
    "There is {count} {name} object.",
    "There are {count} {name} objects.",
    num_objects).format(count=count, name=name)
```

7.14.3 Internationalizing strings in JavaScript code

Each CKAN JavaScript module offers the methods _ and ngettext for translating singular and plural strings, respectively:

```javascript
this.ckan.module('i18n-demo', function($) {
  return {
    initialize: function () {
      console.log(this._('Translate me!'));
      console.log(this.ngettext('%(num)d item', '%(num)d items', 3));
    }
  }
})
```

(continues on next page)
To translate a fixed singular string, use `. It returns the translation of the string for the currently selected locale. If the current locale doesn’t provide a translation for the string then it is returned unchanged.

```javascript
this._('Something that should be translated')
```

Placeholders are supported via `sprintf-sytax`, the corresponding values are passed via another parameter:

```javascript
this._("My name is %s and I'm from %s.",
{name: 'Sarah', hometown: 'Cape Town'})
```

`ngettext` allows you to translate a string that may be either singular or plural, depending on some variable:

```javascript
this.ngettext('Deleted %d item',
  'Deleted %d items',
items.length)
```

If `items.length` is 1 then the translation for the first argument will be returned, otherwise that of the second argument. `num` is a magical placeholder that is automatically provided by `ngettext` and contains the value of the third parameter.

Like `__`, `ngettext` can take additional placeholders:

```javascript
this.ngettext("I'm %s and I'm %d year old",
  "I'm %s and I'm %d years old",
age,
  {name: 'John'})
```

Note: CKAN’s JavaScript code automatically downloads the appropriate translations at request time from the CKAN server. Since CKAN 2.7 the corresponding translation files are regenerated automatically if necessary when CKAN starts.

You can also regenerate the translation files manually using `paster trans js`:

```bash
python setup.py extract_messages  # Extract translatable strings
# Update .po files as desired
python setup.py compile_catalog  # Compile .mo files for Python/Jinja
paster trans js                   # Compile JavaScript catalogs
```

Note: Prior to CKAN 2.7, JavaScript modules received a similar but different `__` function for string translation as a parameter. This is still supported but deprecated and will be removed in a future release.

### 7.14.4 General guidelines for internationalizing strings

Below are some guidelines to follow when marking your strings for translation. These apply to strings in Jinja2 templates or in Python or JavaScript code. These are mostly meant to make life easier for translators, and help to improve the quality of CKAN’s translations:
CKAN documentation, Release 2.8.5

• Leave as much HTML and other code out of the translation string as possible.
For example, don’t include surrounding <p>...</p> tags in the marked string. These aren’t necessary for
the translator to do the translation, and if the translator accidentally changes them in the translation string the
HTML will be broken.
Good:
<p>{% trans %}Don't put HTML tags inside translatable strings{% endtrans %}</p>

Bad (<p> tags don’t need to be in the translation string):
mystring = _("<p>Don't put HTML tags inside translatable strings</p>")

• But don’t split a string into separate strings.
Translators need as much context as possible to translate strings well, and if you split a string up into separate
strings and mark each for translation separately, translators must translate each of these separate strings in
isolation. Also, some languages may need to change the order of words in a sentence or even change the order
of sentences in a paragraph, splitting into separate strings makes assumptions about word order.
It’s better to leave HTML tags or other code in strings than to split a string. For example, it’s often best to leave
HTML <a> tags in rather than split a string.
Good:
_("Don't split a string containing some <b>markup</b> into separate strings.")

Bad (text will be difficult to translate or untranslatable):
_("Don't split a string containing some ") + "<b>" + _("markup") + </b> + _("into
˓→separate strings.")

• You can split long strings over multiple lines using parentheses to avoid long lines, Python will concatenate
them into a single string:
Good:
_("This is a really long string that would just make this line far too "
"long to fit in the window")

• Leave unnecessary whitespace out of translatable strings, but do put punctuation into translatable strings.
• Try not to make translators translate strings that don’t need to be translated.
For example, 'legacy_templates' is the name of a directory, it doesn’t need to be marked for translation.
• Mark singular and plural forms of strings correctly.
In Jinja2 templates this means using {% trans %} and {% pluralize %} or ungettext(). In Python
it means using ungettext(). See above for examples.
Singular and plural forms work differently in different languages. For example English has singular and plural
nouns, but Slovenian has singular, dual and plural.
Good:
num_people = 4
translated_string = ungettext(
'There is one person here',
'There are {num_people} people here',
num_people).format(num_people=num_people)

370

Chapter 7. Contributing guide


Bad (this assumes that all languages have the same plural forms as English):

```python
if num_people == 1:
    translated_string = _('There is one person here')
else:
    translated_string = _('There are {num_people} people here'.format(num_people=num_people))
```

- Don’t use old-style `%s` string formatting in Python, use the new `.format()` method instead.

Strings formatted with `.format()` give translators more context. The `.format()` method is also more expressive, and is the preferred way to format strings in Python 3.

Good:

```python
"Welcome to {site_title}".format(site_title=site_title)
```

Bad (not enough context for translators):

```python
"Welcome to $s" % site_title
```

- Use descriptive names for replacement fields in strings.

This gives translators more context.

Good:

```python
"Welcome to {site_title}".format(site_title=site_title)
```

Bad (not enough context for translators):

```python
"Welcome to {0}".format(site_title)
```

Worse (doesn’t work in Python 2.6):

```python
"Welcome to {}".format(site_title)
```

- Use `TRANSLATORS:` comments to provide extra context for translators for difficult to find, very short, or obscure strings.

For example, in Python:

```python
# TRANSLATORS: This is a helpful comment.
_("This is an ambiguous string")
```

In Jinja2:

```html
{#{ TRANSLATORS: This heading is displayed on the user's profile page. #}
<h1>{% trans %}Heading{% endtrans %}</h1>
```

In JavaScript:

```javascript
// TRANSLATORS: "Manual" refers to the user manual
_("Manual")
```

These comments end up in the `ckan.pot` file and translators will see them when they’re translating the strings (Transifex shows them, for example).
Note: The comment must be on the line before the line with the _(), ungettext() or {% trans %}, and must start with the exact string TRANSLATORS: (in upper-case and with the colon). This string is configured in setup.cfg.

Todo: Explain how to use message contexts, where the same exact string may appear in two different places in the UI but have different meanings.

For example “filter” can be a noun or a verb in English, and may need two different translations in another language. Currently if the string _("filter") appears in different places in CKAN this will only produce one string to be translated in the ckan.pot file.

I think the right way to handle this with gettext is using msgctxt, but it looks like babel doesn’t support it yet.

Todo: Explain how we internationalize dates, currencies and numbers (e.g. different positioning and separators used for decimal points in different languages).

7.15 Unicode handling

This document explains how Unicode and related issues are handled in CKAN. For a general introduction to Unicode and Unicode handling in Python 2 please read the Python 2 Unicode HOWTO. Since Unicode handling differs greatly between Python 2 and Python 3 you might also be interested in the Python 3 Unicode HOWTO.

CKAN uses the six module to provide simultaneous compatibility with Python 2 and Python 3. All strs are Unicode in Python 3 so the builtins unicode and basestring have been removed so there are a few general rules to follow:

1. Change all calls to basestring() into calls to six.string_types()
2. Change remaining instances of basestring to six.string_types
3. Change all instances of (str, unicode) to six.string_types
4. Change all calls to unicode() into calls to six.text_type()
5. Change remaining instances of unicode to six.text_type

These rules do not apply in every instance so some thought needs to be given about the context around these changes.

Note: This document describes the intended future state of Unicode handling in CKAN. For historic reasons, some existing code does not yet follow the rules described here.

New code should always comply with the rules in this document. Exceptions must be documented.

7.15.1 Overall Strategy

CKAN only uses Unicode internally (six.text_type on both Python 2 and Python 3). Conversion to/from ASCII strings happens on the boundary to other systems/libraries if necessary.
7.15.2 Encoding of Python files

Files containing Python source code (*.py) must be encoded using UTF-8, and the encoding must be declared using the following header:

```
# encoding: utf-8
```

This line must be the first or second line in the file. See PEP 263 for details.

7.15.3 String literals

String literals are string values given directly in the source code (as opposed to strings variables read from a file, received via argument, etc.). In Python 2, string literals by default have type `str`. They can be changed to `unicode` by adding a `u` prefix. In addition, the `b` prefix can be used to explicitly mark a literal as `str`:

```
x = "I'm a str literal"
y = u"I'm a unicode literal"
z = b"I'm also a str literal"
```

In Python 3, all `str` are Unicode and `str` and `bytes` are explicitly different data types so:

```
x = "I'm a str literal"
y = u"I'm also a str literal"
z = b"I'm a bytes literal"
```

In CKAN, every string literal must carry either a `u` or a `b` prefix. While the latter is redundant in Python 2, it makes the developer’s intention explicit and eases a future migration to Python 3.

This rule also holds for `raw strings`, which are created using an `r` prefix. Simply use `ur` instead:

```
m = re.match(ur'A \s+Unicode \s+pattern')
```

For more information on string prefixes please refer to the Python documentation.

**Note:** The `unicode_literals` future statement is *not* used in CKAN.

7.15.4 Best Practices

**Use `io.open` to open text files**

When opening text (not binary) files you should use `io.open` instead of `open`. This allows you to specify the file’s encoding and reads will return Unicode instead of ASCII:

```python
import io

with io.open(u'my_file.txt', u'r', encoding=u'utf-8') as f:
    text = f.read()  # contents is automatically decoded
                    # to Unicode using UTF-8
```

Text files should be encoded using UTF-8 if possible.
Normalize strings before comparing them

For many characters, Unicode offers multiple descriptions. For example, a small latin e with an acute accent (é) can either be specified using its dedicated code point (U+00E9) or by combining the code points for e (U+0065) and the accent (U+0301). Both variants will look the same but are different from a numerical point of view:

```python
>>> x = u'\N{LATIN SMALL LETTER E WITH ACUTE}''
>>> y = u'\N{LATIN SMALL LETTER E}\N{COMBINING ACUTE ACCENT}''
>>> print x, y
é e
>>> print repr(x), repr(y)
'u'\xe9'  u'e\u0301'
>>> x == y
False
```

Therefore, if you want to compare two Unicode strings based on their characters you need to normalize them first using `unicodedata.normalize`:

```python
>>> from unicodedata import normalize
>>> x_norm = normalize(u'NFC', x)
>>> y_norm = normalize(u'NFC', y)
>>> print x_norm, y_norm
é é
>>> print repr(x_norm), repr(y_norm)
'u'\xe9'  u'\xe9'
>>> x_norm == y_norm
True
```

Use the Unicode flag in regular expressions

By default, the character classes of Python’s `re` module (\w, \d, ...) only match ASCII-characters. For example, \w (alphanumeric character) does, by default, not match ö:

```python
>>> print re.match(ur'^\w$', u'ö')
None
```

Therefore, you need to explicitly activate Unicode mode by passing the `re.U` flag:

```python
>>> print re.match(ur'^\w$', u'ö', re.U)
<_sre.SRE_Match object at 0xb60ea2f8>
```

Note: Some functions (e.g. `re.split` and `re.sub`) take additional optional parameters before the flags, so you should pass the flag via a keyword argument:

```python
replaced = re.sub(ur'\W', u'_', original, flags=re.U)
```

The type of the values returned by `re.split`, `re.MatchObject.group`, etc. depends on the type of the input string:

```python
>>> re.split(ur'\W+', b'Just a string!', flags=re.U)
['Just', 'a', 'string', '']
>>> re.split(ur'\W+', u'Just some Unicode!', flags=re.U)
[u'Just', u'some', u'Unicode', u'']
```
Note that the type of the *pattern string* does not influence the return type.

### Filenames

Like all other strings, filenames should be stored as Unicode strings internally. However, some filesystem operations return or expect byte strings, so filenames have to be encoded/decoded appropriately. Unfortunately, different operating systems use different encodings for their filenames, and on some of them (e.g. Linux) the file system encoding is even configurable by the user.

To make decoding and encoding of filenames easier, the `ckan.lib.io` module therefore contains the functions `decode_path` and `encode_path`, which automatically use the correct encoding:

```python
import io
import json
from ckan.lib.io import decode_path

# __file__ is a byte string, so we decode it
MODULE_FILE = decode_path(__file__)
print(u'Running from ' + MODULE_FILE)

# The functions in os.path return unicode if given unicode
MODULE_DIR = os.path.dirname(MODULE_FILE)
DATA_FILE = os.path.join(MODULE_DIR, u'data.json')

# Most of Python's built-in I/O-functions accept Unicode filenames as input
# and encode them automatically
with io.open(DATA_FILE, encoding='utf-8') as f:
    data = json.load(f)
```

Note that almost all Python’s built-in I/O-functions accept Unicode filenames as input and encode them automatically, so using `encode_path` is usually not necessary.

The return type of some of Python’s I/O-functions (e.g. `os.listdir` and `os.walk`) depends on the type of their input: If passed byte strings they return byte strings and if passed Unicode they automatically decode the raw filenames to Unicode before returning them. Other functions exist in two variants that return byte strings (e.g. `os.getcwd`) and Unicode (e.g. `os.getcwdu`), respectively.

**Warning:** Some of Python’s I/O-functions may return *both* byte and Unicode strings for a single call. For example, `os.listdir` will normally return Unicode when passed Unicode, but filenames that cannot be decoded using the filesystem encoding will still be returned as byte strings!

Note that if the filename of an existing file cannot be decoded using the filesystem’s encoding then the environment Python is running in is most probably incorrectly set up.

The instructions above are meant for the names of existing files that are obtained using Python’s I/O functions. However, sometimes one also wants to create new files whose names are generated from unknown sources (e.g. user input). To make sure that the generated filename is safe to use and can be represented using the filesystem’s encoding use `ckan.lib.munge.munge_filename`:

```python
>> ckan.lib.munge.munge_filename(u'Data from Linköping (year: 2016).txt')
'u'data-from-linkoping-year-2016.txt'
```
7.16 Testing coding standards

All new code, or changes to existing code, should have new or updated tests before being merged into master. This document gives some guidelines for developers who are writing tests or reviewing code for CKAN.

See also:
- Testing CKAN  How to set up your development environment to run CKAN’s test suite
- Testing code that uses background jobs  How to handle asynchronous background jobs in your tests

7.16.1 Transitioning from legacy to new tests

CKAN is an old code base with a large legacy test suite in ckan.tests.legacy. The legacy tests are difficult to maintain and extend, but are too many to be replaced all at once in a single effort. So we’re following this strategy:

1. A new test suite has been started in ckan.tests.
2. For now, we’ll run both the legacy tests and the new tests before merging something into the master branch.
3. Whenever we add new code, or change existing code, we’ll add new-style tests for it.
4. If you change the behavior of some code and break some legacy tests, consider adding new tests for that code and deleting the legacy tests, rather than updating the legacy tests.
5. Now and then, we’ll write a set of new tests to cover part of the code, and delete the relevant legacy tests. For example if you want to refactor some code that doesn’t have good tests, write a set of new-style tests for it first, refactor, then delete the relevant legacy tests.

In this way we can incrementally extend the new tests to cover CKAN one “island of code” at a time, and eventually we can delete the legacy ckan.tests directory entirely.

7.16.2 Guidelines for writing new-style tests

We want the tests in ckan.tests to be:

Fast
- Don’t share setup code between tests (e.g. in test class setup() or setup_class() methods, saved against the self attribute of test classes, or in test helper modules).

  Instead write helper functions that create test objects and return them, and have each test method call just the helpers it needs to do the setup that it needs.
- Where appropriate, use the mock library to avoid pulling in other parts of CKAN (especially the database), see Mocking: the mock library.

Independent
- Each test module, class and method should be able to be run on its own.
- Tests shouldn’t be tightly coupled to each other, changing a test shouldn’t affect other tests.
Clear  It should be quick and easy to see what went wrong when a test fails, or to see what a test does and how it works if you have to debug or update a test. If you think the test or helper method isn’t clear by itself, add docstrings. You shouldn’t have to figure out what a complex test method does, or go and look up a lot of code in other files to understand a test method.

- Tests should follow the canonical form for a unit test, see Recipe for a test method.
- Write lots of small, simple test methods not a few big, complex tests.
- Each test method should test just One Thing.
- The name of a test method should clearly explain the intent of the test. See Naming test methods.

Easy to find  It should be easy to know where to add new tests for some new or changed code, or to find the existing tests for some code.

- See How should tests be organized?
- See Naming test methods.

Easy to write  Writing lots of small, clear and simple tests that all follow similar recipes and organization should make tests easy to write, as well as easy to read.

The follow sections give some more specific guidelines and tips for writing CKAN tests.

How should tests be organized?

The organization of test modules in ckan.tests mirrors the organization of the source modules in ckan:

```
ckan/
 tests/
 controllers/
   test_package.py <-- Tests for ckan/controllers/package.py
   ...
 lib/
   test_helpers.py <-- Tests for ckan/lib/helpers.py
   ...
 logic/
   action/
   test_get.py
   ...
 auth/
   test_get.py
   ...
   test_converters.py
   test_validators.py
 migration/
   versions/
   test_001_add_existing_tables.py
   ...
 model/
   test_package.py
   ...
```

There are a few exceptional test modules that don’t fit into this structure, for example PEP8 tests and coding standards tests. These modules can just go in the top-level ckan/tests/ directory. There shouldn’t be too many of these.
Naming test methods

The name of a test method should clearly explain the intent of the test.

Test method names are printed out when tests fail, so the user can often see what went wrong without having to look into the test file. When they do need to look into the file to debug or update a test, the test name helps to clarify the test.

Do this even if it means your method name gets really long, since we don’t write code that calls our test methods there’s no advantage to having short test method names.

Some modules in CKAN contain large numbers of loosely related functions. For example, `ckan.logic.action.update` contains all functions for updating things in CKAN. This means that `ckan.tests.logic.action.test_update` is going to contain an even larger number of test functions.

So as well as the name of each test method explaining the intent of the test, tests should be grouped by a test class that aggregates tests against a model entity or action type, for instance:

```python
class TestPackageCreate(object):
    # ...
    def test_it_validates_name(self):
        # ...
    def test_it_validates_url(self):
        # ...

class TestResourceCreate(object):
    # ...
    def test_it_validates_package_id(self):
        # ...
```

Good test names:

- `TestUserUpdate.test_update_with_id_that_does_not_exist`
- `TestUserUpdate.test_update_with_no_id`
- `TestUserUpdate.test_update_with_invalid_name`

Bad test names:

- `test_user_update`
- `test_update_pkg_1`
- `test_package`

Recipe for a test method

The Pylons Unit Testing Guidelines give the following recipe for all unit test methods to follow:

1. Set up the preconditions for the method / function being tested.
2. Call the method / function exactly one time, passing in the values established in the first step.
3. Make assertions about the return value, and / or any side effects.
4. Do absolutely nothing else.
Most CKAN tests should follow this form. Here’s an example of a simple action function test demonstrating the recipe:

```python
def test_user_update_name(self):
    '''Test that updating a user’s name works successfully.'''

    # The canonical form of a test has four steps:
    # 1. Setup any preconditions needed for the test.
    # 2. Call the function that’s being tested, once only.
    # 3. Make assertions about the return value and/or side-effects of
    #    of the function that’s being tested.
    # 4. Do nothing else!

    # 1. Setup.
    user = factories.User()
    user['name'] = 'updated'

    # 2. Make assertions about the return value and/or side-effects.
    assert_raises(logic.ValidationError,
                  helpers.call_action, 'user_update', **user)
```

One common exception is when you want to use a `for` loop to call the function being tested multiple times, passing it lots of different arguments that should all produce the same return value and/or side effects. For example, this test from `ckan.tests.logic.action.test_update`:

```python
def test_user_update_with_invalid_name(self):
    user = factories.User()

    invalid_names = ('', 'a', False, 0, -1, 23, 'new', 'edit', 'search',
                     'a' * 200, 'Hi!', 'i++%')
    for name in invalid_names:
        user['name'] = name
        assert_raises(logic.ValidationError,
                      helpers.call_action, 'user_update', **user)
```

The behavior of `user_update()` is the same for every invalid value. We do want to test `user_update()` with lots of different invalid names, but we obviously don’t want to write a dozen separate test methods that are all the same apart from the value used for the invalid user name. We don’t really want to define a helper method and a dozen test methods that call it either. So we use a simple loop. Technically this test calls the function being tested more than once, but there’s only one line of code that calls it.

**How detailed should tests be?**

Generally, what we’re trying to do is test the *interfaces* between modules in a way that supports modularization: if you change the code within a function, method, class or module, if you don’t break any of that code’s tests you should be able to expect that CKAN as a whole will not be broken.

As a general guideline, the tests for a function or method should:

- Test for success:
  - Test the function with typical, valid input values
– Test with valid, edge-case inputs
– If the function has multiple parameters, test them in different combinations

• Test for failure:
  – Test that the function fails correctly (e.g. raises the expected type of exception) when given likely invalid inputs (for example, if the user passes an invalid user_id as a parameter)
  – Test that the function fails correctly when given bizarre input

• Test that the function behaves correctly when given unicode characters as input
• Cover the interface of the function: test all the parameters and features of the function

Creating test objects: ckan.tests.factories

This is a collection of factory classes for building CKAN users, datasets, etc.
These are meant to be used by tests to create any objects that are needed for the tests. They’re written using factory_boy:
http://factoryboy.readthedocs.org/en/latest/

These are not meant to be used for the actual testing, e.g. if you’re writing a test for the user_create() function then call call_action(), don’t test it via the User factory below.

Usage:

```python
# Create a user with the factory's default attributes, and get back a user dict:
user_dict = factories.User()

# You can create a second user the same way. For attributes that can't be the same (e.g. you can't have two users with the same name) a new value will be generated each time you use the factory:
another_user_dict = factories.User()

# Create a user and specify your own user name and email (this works with any params that CKAN's user_create() accepts):
custom_user_dict = factories.User(name='bob', email='bob@bob.com')

# Get a user dict containing the attributes (name, email, password, etc.) that the factory would use to create a user, but without actually creating the user in CKAN:
user_attributes_dict = factories.User.attributes()

# If you later want to create a user using these attributes, just pass them to the factory:
user = factories.User(**user_attributes_dict)
```

class ckan.tests.factories.User
A factory class for creating CKAN users.

class ckan.tests.factories.Resource
A factory class for creating CKAN resources.

class ckan.tests.factories.ResourceView
A factory class for creating CKAN resource views.
Note: if you use this factory, you need to load the `image_view` plugin on your test class (and unload it later), otherwise you will get an error.

Example:

```python
class TestSomethingWithResourceViews(object):
    @classmethod
    def setup_class(cls):
        if not p.plugin_loaded('image_view'):
            p.load('image_view')

    @classmethod
    def teardown_class(cls):
        p.unload('image_view')
```

class ckan.tests.factories.Sysadmin
A factory class for creating sysadmin users.

class ckan.tests.factories.Group
A factory class for creating CKAN groups.

class ckan.tests.factories.Organization
A factory class for creating CKAN organizations.

class ckan.tests.factories.Dataset
A factory class for creating CKAN datasets.

class ckan.tests.factories.MockUser
A factory class for creating mock CKAN users using the mock library.

**FACTORY_FOR**

alias of mock.mock.MagicMock

class ckan.tests.factories.SystemInfo
A factory class for creating SystemInfo objects (config objects stored in the DB).

can.tests.factories.validator_data_dict()
Return a data dict with some arbitrary data in it, suitable to be passed to validator functions for testing.

can.tests.factories.validator_errors_dict()
Return an errors dict with some arbitrary errors in it, suitable to be passed to validator functions for testing.

class ckan.tests.factories.Vocabulary
A factory class for creating tag vocabularies.

**Test helper functions: ckan.tests.helpers**

This is a collection of helper functions for use in tests.

We want to avoid sharing test helper functions between test modules as much as possible, and we definitely don’t want to share test fixtures between test modules, or to introduce a complex hierarchy of test class subclasses, etc.

We want to reduce the amount of “travel” that a reader needs to undertake to understand a test method – reducing the number of other files they need to go and read to understand what the test code does. And we want to avoid tightly coupling test modules to each other by having them share code.

But some test helper functions just increase the readability of tests so much and make writing tests so much easier, that it’s worth having them despite the potential drawbacks.

This module is reserved for these very useful functions.
ckan.tests.helpers.reset_db()
Reset CKAN's database.

If a test class uses the database, then it should call this function in its setup() method to make sure that it has a clean database to start with (nothing left over from other test classes or from previous test runs).

If a test class doesn’t use the database (and most test classes shouldn’t need to) then it doesn’t need to call this function.

Returns None

ckan.tests.helpers.call_action(action_name, context=None, **kwargs)
Call the named ckan.logic.action function and return the result.

This is just a nicer way for user code to call action functions, nicer than either calling the action function directly or via ckan.logic.get_action().

For example:

```python
user_dict = call_action('user_create', name='seanh',
                       email='seanh@seanh.com', password='pass')
```

Any keyword arguments given will be wrapped in a dict and passed to the action function as its data_dict argument.

Note: this skips authorization! It passes 'ignore_auth': True to action functions in their context dicts, so the corresponding authorization functions will not be run. This is because ckan.tests.logic.action tests only the actions, the authorization functions are tested separately in ckan.tests.logic.auth. See the testing guidelines for more info.

This function should eventually be moved to ckan.logic.call_action() and the current ckan.logic.get_action() function should be deprecated. The tests may still need their own wrapper function for ckan.logic.call_action(), e.g. to insert 'ignore_auth': True into the context dict.

Parameters

• action_name (string) – the name of the action function to call, e.g. 'user_update'

• context (dict) – the context dict to pass to the action function (optional, if no context is given a default one will be supplied)

Returns the dict or other value that the action function returns

ckan.tests.helpers.call_auth(auth_name, context, **kwargs)
Call the named ckan.logic.auth function and return the result.

This is just a convenience function for tests in ckan.tests.logic.auth to use.

Usage:

```python
result = helpers.call_auth('user_update', context=context,
                           id='some_user_id',
                           name='updated_user_name')
```

Parameters

• auth_name (string) – the name of the auth function to call, e.g. 'user_update'

• context (dict) – the context dict to pass to the auth function, must contain 'user' and 'model' keys, e.g. {'user': 'fred', 'model': my_mock_model_object}
Returns the dict that the auth function returns, e.g. {'success': True} or {'success': False, msg: '...'} or just {'success': False}

Return type dict

```python
class ckan.tests.helpers.CKANTestApp(app, extra_environ=None, relative_to=None, use_unicode=True)
```
A wrapper around webtest.TestApp

It adds some convenience methods for CKAN

```python
class ckan.tests.helpers.FunctionalTestBase
```
A base class for functional test classes to inherit from.

Allows configuration changes by overriding _apply_config_changes and resetting the CKAN config after your test class has run. It creates a webtest.TestApp at self.app for your class to use to make HTTP requests to the CKAN web UI or API. Also loads plugins defined by _load_plugins in the class definition.

If you’re overriding methods that this class provides, like setup_class() and teardown_class(), make sure to use super() to call this class’s methods at the top of yours!

```python
setup()
```
Reset the database and clear the search indexes.

```python
class ckan.tests.helpers.RQTestBase
```
Base class for tests of RQ functionality.

```python
setup()
```
Delete all RQ queues and jobs.

```python
all_jobs()
```
Get a list of all RQ jobs.

```python
enqueue(job=None, *args, **kwargs)
```
Enqueue a test job.

```python
class ckan.tests.helpers.FunctionalRQTestBase
```
Base class for functional tests of RQ functionality.

```python
setup()
```
Reset the database and clear the search indexes.

```python
ckan.tests.helpers.submit_and_follow(app, form, extra_environ=None, name=None, value=None, **args)
```
Call webtest_submit with name/value passed expecting a redirect and return the response from following that redirect.

```python
ckan.tests.helpers.webtest_submit(form, name=None, index=None, value=None, **args)
```
backported version of webtest.Form.submit that actually works for submitting with different submit buttons.

We’re stuck on an old version of webtest because we’re stuck on an old version of webob because we’re stuck on an old version of Pylons. This prolongs our suffering, but on the bright side it lets us have functional tests that work.

```python
ckan.tests.helpers.webtest_submit_fields(form, name=None, index=None, submit_value=None)
```
backported version of webtest.Form.submit_fields that actually works for submitting with different submit buttons.

```python
ckan.tests.helpers.webtest_maybe_follow(response, **kw)
```
Follow all redirects. If this response is not a redirect, do nothing. Returns another response object.

(backported from WebTest 2.0.1)
ckan.tests.helpers.change_config(key, value)

Decorator to temporarily change CKAN's config to a new value.

This allows you to easily create tests that need specific config values to be set, making sure it'll be reverted to what it was originally, after your test is run.

Usage:

```python
@helpers.change_config('ckan.site_title', 'My Test CKAN')
def test_ckan_site_title(self):
    assert config['ckan.site_title'] == 'My Test CKAN'
```

Parameters

- **key (string)** – the config key to be changed, e.g. 'ckan.site_title'
- **value (string)** – the new config key's value, e.g. 'My Test CKAN'

See also:

The context manager changed_config()

ckan.tests.helpers.changed_config(*args, **kwds)

Context manager for temporarily changing a config value.

Allows you to temporarily change the value of a CKAN configuration option. The original value is restored once the context manager is left.

Usage:

```python
with changed_config(u'ckan.site_title', u'My Test CKAN'):
    assert config[u'ckan.site_title'] == u'My Test CKAN'
```

See also:

The decorator change_config()

ckan.tests.helpers.mock_auth(auth_function_path)

Decorator to easily mock a CKAN auth method in the context of a test function.

It adds a mock object for the provided auth_function_path as a parameter to the test function.

Essentially it makes sure that ckan.auth.clear_auth_functions_cache is called before and after to make sure that the auth functions pick up the newly changed values.

Usage:

```python
@helpers.mock_auth('ckan.logic.auth.create.package_create')
def test_mock_package_create(self, mock_package_create):
    from ckan import logic
    mock_package_create.return_value = {'success': True}

    # package_create is mocked
    eq_(logic.check_access('package_create', {}), True)

    assert mock_package_create.called
```

Parameters **action_name (string)** – the full path to the auth function to be mocked, e.g. ckan.logic.auth.create.package_create
ckan.tests.helpers.mock_action(*action_name*)

Decorator to easily mock a CKAN action in the context of a test function

It adds a mock object for the provided action as a parameter to the test function. The mock is discarded at the end of the function, even if there is an exception raised.

Note that this mocks the action both when it’s called directly via ckan.logic.get_action and via ckan.plugins.toolkit.get_action.

Usage:

```python
@mock_action('user_list')
def test_mock_user_list(self, mock_user_list):
    mock_user_list.return_value = 'hi'
    # user_list is mocked
    eq_(helpers.call_action('user_list', {}), 'hi')
    assert mock_user_list.called
```

**Parameters**

- **action_name** *(string)* – the name of the action to be mocked, e.g. package_create

ckan.tests.helpers.set_extra_environ(*key, value*)

Decorator to temporarily changes a single request environment value

Create a new test app and use the a side effect of making a request to set an extra_environ value. Reset the value to ’’ after the test.

Usage:

```python
@helpers.extra_environ('SCRIPT_NAME', '/myscript')
def test_ckan_thing_affected_by_script_name(self):
    # ...
```

**Parameters**

- **key** *(string)* – the extra_environ key to be changed, e.g. 'SCRIPT_NAME'
- **value** *(string)* – the new extra_environ key's value, e.g. '/myscript'

ckan.tests.helpers.recorded_logs(*args, **kwds*)

Context manager for recording log messages.

**Parameters**

- **logger** – The logger to record messages from. Can either be a `logging.Logger` instance or a string with the logger’s name. Defaults to the root logger.
- **level** *(int)* – Temporary log level for the target logger while the context manager is active. Pass `None` if you don’t want the level to be changed. The level is automatically reset to its original value when the context manager is left.
- **override_disabled** *(bool)* – A logger can be disabled by setting its disabled attribute. By default, this context manager sets that attribute to `False` at the beginning of its execution and resets it when the context manager is left. Set `override_disabled` to `False` to keep the current value of the attribute.
• **override_global_level**(bool) – The `logging.disable` function allows one to install a global minimum log level that takes precedence over a logger’s own level. By default, this context manager makes sure that the global limit is at most `level`, and reduces it if necessary during its execution. Set `override_global_level` to `False` to keep the global limit.

**Returns** A recording log handler that listens to `logger` during the execution of the context manager.

**Return type** *RecordingLogHandler*

Example:

```python
import logging

logger = logging.getLogger(__name__)

with recorded_logs(logger) as logs:
    logger.info(u'Hello, world!')

logs.assert_log(u'info', u'world')
```

class ckan.tests.helpers.RecordingLogHandler(*args, **kwargs)

Log handler that records log messages for later inspection.

You can inspect the recorded messages via the `messages` attribute (a dict that maps log levels to lists of messages) or by using `assert_log`.

This class is rarely useful on its own, instead use `recorded_logs()` to temporarily record log messages.

**emit**(record)

Do whatever it takes to actually log the specified logging record.

This version is intended to be implemented by subclasses and so raises a `NotImplementedError`.

**assert_log**(level, pattern, msg=None)

Assert that a certain message has been logged.

**Parameters**

• **pattern**(string) – A regex which the message has to match. The match is done using `re.search`.

• **level**(string) – The message level (`'debug'`, ...).

• **msg**(string) – Optional failure message in case the expected log message was not logged.

**Raises** *AssertionError* – If the expected message was not logged.

clear()

Clear all captured log messages.

**Mocking: the mock library**

We use the mock library to replace parts of CKAN with mock objects. This allows a CKAN function to be tested independently of other parts of CKAN or third-party libraries that the function uses. This generally makes the test simpler and faster (especially when `ckan.model` is mocked out so that the tests don’t touch the database). With mock objects we can also make assertions about what methods the function called on the mock object and with which arguments.
Note: Overuse of mocking is discouraged as it can make tests difficult to understand and maintain. Mocking can be useful and make tests both faster and simpler when used appropriately. Some rules of thumb:

- Don’t mock out more than one or two objects in a single test method.

- Don’t use mocking in more functional-style tests. For example the action function tests in `ckan.tests.logic.action` and the frontend tests in `ckan.tests.controllers` are functional tests, and probably shouldn’t do any mocking.

- Do use mocking in more unit-style tests. For example the authorization function tests in `ckan.tests.logic.auth`, the converter and validator tests in `ckan.tests.logic.auth`, and most (all?) lib tests in `ckan.tests.lib` are unit tests and should use mocking when necessary (often it’s possible to unit test a method in isolation from other CKAN code without doing any mocking, which is ideal).

In these kind of tests we can often mock one or two objects in a simple and easy to understand way, and make the test both simpler and faster.

A mock object is a special object that allows user code to access any attribute name or call any method name (and pass any parameters) on the object, and the code will always get another mock object back:

```python
>>> import mock
>>> my_mock = mock.MagicMock()
>>> my_mock.foo
<MockMock name='mock.foo' id='56032400'>
>>> my_mock.bar
<MockMock name='mock.bar' id='54093968'>
>>> my_mock.foobar()
<MockMock name='mock.foobar()' id='54115664'>
>>> my_mock.foobar(1, 2, 'barfoo')
<MockMock name='mock.foobar()' id='54115664'>
```

When a test needs a mock object to actually have some behavior besides always returning other mock objects, it can set the value of a certain attribute on the mock object, set the return value of a certain method, specify that a certain method should raise a certain exception, etc.

You should read the mock library’s documentation to really understand what’s going on, but here’s an example of a test from `ckan.tests.logic.auth.test_update` that tests the `user_update()` authorization function and mocks out `ckan.model`:

```python
def test_user_update_user_cannot_update_another_user(self):
    '''Users should not be able to update other users' accounts.'''

    # 1. Setup.
    # Make a mock ckan.model.User object, Fred.
    fred = factories.MockUser(name='fred')

    # Make a mock ckan.model object.
    mock_model = mock.MagicMock()
    # model.User.get(user_id) should return Fred.
    mock_model.User.get.return_value = fred
    mock_model.User.get.return_value = fred

    # Put the mock model in the context.
    # This is easier than patching import ckan.model.
    context = {'model': mock_model}
```

(continues on next page)
# The logged-in user is going to be Bob, not Fred.
context['user'] = 'bob'

# 2. Call the function that's being tested, once only.

# Make Bob try to update Fred's user account.
params = {
    'id': fred.id,
    'name': 'updated_user_name',
}

# 3. Make assertions about the return value and/or side-effects.

nose.tools.assert_raises(logic.NotAuthorized, helpers.call_auth,
                        'user_update', context=context, **params)

# 4. Do nothing else!

The following sections will give specific guidelines and examples for writing tests for each module in CKAN.

Note: When we say that all functions should have tests in the sections below, we mean all public functions that the module or class exports for use by other modules or classes in CKAN or by extensions or templates.

Private helper methods (with names beginning with _) never have to have their own tests, although they can have tests if helpful.

Writing ckan.logic.action tests

All action functions should have tests.

Most action function tests will be high-level tests that both test the code in the action function itself, and also indirectly test the code in ckan.lib, ckan.model, ckan.logic.schema etc. that the action function calls. This means that most action function tests should not use mocking.

Tests for action functions should use the ckan.tests.helpers.call_action() function to call the action functions.

One thing call_action() does is to add ignore_auth: True into the context dict that’s passed to the action function, so that CKAN will not call the action function’s authorization function. The tests for an action function don’t need to cover authorization, because the authorization functions have their own tests in ckan.tests.logic.auth. But action function tests do need to cover validation, more on that later.

Action function tests should test the logic of the actions themselves, and should test validation (e.g. that various kinds of valid input work as expected, and invalid inputs raise the expected exceptions).

Here’s an example of a simple ckan.logic.action test:

def test_user_update_name(self):
    '''Test that updating a user’s name works successfully.'''

    # The canonical form of a test has four steps:
# 1. Setup any preconditions needed for the test.
# 2. Call the function that’s being tested, once only.
# 3. Make assertions about the return value and/or side-effects of
# of the function that’s being tested.
# 4. Do nothing else!

# 1. Setup.
user = factories.User()
user['name'] = 'updated'

# 2. Make assertions about the return value and/or side-effects.
assert_raises(logic.ValidationError,
              helpers.call_action, 'user_update',
              **user)

Todo: Insert the names of all tests for ckan.logic.action.update.user_update, for example, to show what level of detail things should be tested in.

Writing `ckan.logic.auth` tests

All auth functions should have tests.

Most auth function tests should be unit tests that test the auth function in isolation, without bringing in other parts of CKAN or touching the database. This requires using the mock library to mock `ckan.model`, see `Mocking: the mock library`.

Tests for auth functions should use the `ckan.tests.helpers.call_auth()` function to call auth functions. Here’s an example of a simple `ckan.logic.auth` test:

```python
def test_user_update_user_cannot_update_another_user(self):
    '''Users should not be able to update other users' accounts.'''

    # 1. Setup.
    # Make a mock ckan.model.User object, Fred.
    fred = factories.MockUser(name='fred')

    # Make a mock ckan.model object.
    mock_model = mock.MagicMock()
    # model.User.get(user_id) should return Fred.
    mock_model.User.get.return_value = fred

    # Put the mock model in the context.
    # This is easier than patching import ckan.model.
    context = {'model': mock_model}

    # The logged-in user is going to be Bob, not Fred.
    context['user'] = 'bob'

    # 2. Call the function that’s being tested, once only.
```
# Make Bob try to update Fred's user account.
params = {
    'id': fred.id,
    'name': 'updated_user_name',
}

# 3. Make assertions about the return value and/or side-effects.
nose.tools.assert_raises(logic.NotAuthorized, helpers.call_auth,
    'user_update', context=context, **params)

# 4. Do nothing else!

Writing converter and validator tests

All converter and validator functions should have unit tests.

Although these converter and validator functions are tested indirectly by the action function tests, this may not catch all the converters and validators and all their options, and converters and validators are not only used by the action functions but are also available to plugins. Having unit tests will also help to clarify the intended behavior of each converter and validator.

CKAN’s action functions call ckan.lib.navl.dictization_functions.validate() to validate data posted by the user. Each action function passes a schema from ckan.logic.schema to validate(). The schema gives validate() lists of validation and conversion functions to apply to the user data. These validation and conversion functions are defined in ckan.logic.validators, ckan.logic.converters and ckan.lib.navl.validators.

Most validator and converter tests should be unit tests that test the validator or converter function in isolation, without bringing in other parts of CKAN or touching the database. This requires using the mock library to mock ckan.model, see Mocking: the mock library.

When testing validators, we often want to make the same assertions in many tests: assert that the validator didn’t modify the data dict, assert that the validator didn’t modify the errors dict, assert that the validator raised Invalid, etc. Decorator functions are defined at the top of validator test modules like ckan.tests.logic.test_validators to make these common asserts easy. To use one of these decorators you have to:

1. Define a nested function inside your test method, that simply calls the validator function that you’re trying to test.
2. Apply the decorators that you want to this nested function.
3. Call the nested function.

Here’s an example of a simple validator test that uses this technique:

```python
def test_user_name_validator_with_non_string_value(self):
    '''user_name_validator() should raise Invalid if given a non-string value.'''

    non_string_values = [13, 23.7],
```
100,
1.0j,
None,
True,
False,
('a', 2, False),
[13, None, True],
{'foo': 'bar'},
lambda x: x ** 2,
]

# Mock ckan.model.
mock_model = mock.MagicMock()
# model.User.get(some_user_id) needs to return None for this test.
mock_model.User.get.return_value = None

key = ('name',)
for non_string_value in non_string_values:
data = factories.validator_data_dict()
data[key] = non_string_value
errors = factories.validator_errors_dict()
errors[key] = []

@t.does_not_modify_data_dict
@raises_Invalid
def call_validator(*args, **kwargs):
    return validators.user_name_validator(*args, **kwargs)
call_validator(key, data, errors, context={'model': mock_model})

No tests for ckan.logic.schema.py

We don’t write tests for the schemas defined in ckan.logic.schema. The validation done by the schemas is instead tested indirectly by the action function tests. The reason for this is that CKAN actually does validation in multiple places: some validation is done using schemas, some validation is done in the action functions themselves, some is done in dictization, and some in the model. By testing all the different valid and invalid inputs at the action function level, we catch it all in one place.

Writing ckan.controllers tests

Controller tests probably shouldn’t use mocking.

Todo: Write the tests for one controller, figuring out the best way to write controller tests. Then fill in this guidelines section, using the first set of controller tests as an example.

Some things have been decided already:

- All controller methods should have tests
- Controller tests should be high-level tests that work by posting simulated HTTP requests to CKAN URLs and testing the response. So the controller tests are also testing CKAN’s templates and rendering - these are CKAN’s front-end tests.

For example, maybe we use a webtests testapp and then use beautiful soup to parse the HTML?
In general the tests for a controller shouldn’t need to be too detailed, because there shouldn’t be a lot of complicated logic and code in controller classes. The logic should be handled in other places such as ckan.logic and ckan.lib, where it can be tested easily and also shared with other code.

The tests for a controller should:

- Make sure that the template renders without crashing.
- Test that the page contents seem basically correct, or test certain important elements in the page contents (but don’t do too much HTML parsing).
- Test that submitting any forms on the page works without crashing and has the expected side-effects.
- When asserting side-effects after submitting a form, controller tests should use the ckan.tests.helpers.call_action() function. For example after creating a new user by submitting the new user form, a test could call the user_show() action function to verify that the user was created with the correct values.

Warning: Some CKAN controllers do contain a lot of complicated logic code. These controllers should be refactored to move the logic into ckan.logic or ckan.lib where it can be tested easily. Unfortunately in cases like this it may be necessary to write a lot of controller tests to get this code’s behavior into a test harness before it can be safely refactored.

Writing ckan.model tests

All model methods should have tests.

Todo: Write the tests for one ckan.model module, figuring out the best way to write model tests. Then fill in this guidelines section, using the first set of model tests as an example.

Writing ckan.lib tests

All lib functions should have tests.

Todo: Write the tests for one ckan.lib module, figuring out the best way to write lib tests. Then fill in this guidelines section, using the first

We probably want to make these unit tests rather than high-level tests and mock out ckan.model, so the tests are really fast and simple.

Note that some things in lib are particularly important, e.g. the functions in ckan.lib.helpers are exported for templates (including extensions) to use, so all of these functions should really have tests and docstrings. It’s probably worth focusing on these modules first.

Writing ckan.plugins tests

The plugin interfaces in ckan.plugins.interfaces are not directly testable because they don’t contain any code, but:
• Each plugin interface should have an example plugin in `ckan.ckanext` and the example plugin should have its own functional tests.

• The tests for the code that calls the plugin interface methods should test that the methods are called correctly.

For example `ckan.logic.action.get.package_show()` calls `ckan.plugins.interfaces.IDatasetForm.read()`, so the `package_show()` tests should include tests that `read()` is called at the right times and with the right parameters.

Everything in `ckan.plugins.toolkit` should have tests, because these functions are part of the API for extensions to use. But `toolkit` imports most of these functions from elsewhere in CKAN, so the tests should be elsewhere also, in the test modules for the modules where the functions are defined.

Other than the plugin interfaces and plugins toolkit, any other code in `ckan.plugins` should have tests.

**Writing ckan.migration tests**

All migration scripts should have tests.

**Todo:** Write some tests for a migration script, and then use them as an example to fill out this guidelines section.

**Writing ckan.ckanext tests**

Within extensions, follow the same guidelines as for CKAN core. For example if an extension adds an action function then the action function should have tests, etc.

### 7.17 Frontend development guidelines

#### 7.17.1 Templating

Within CKAN 2.0 we moved out templating to use Jinja2 from Genshi. This was done to provide a more flexible, extensible and most importantly easy to understand templating language.

Some useful links to get you started.

- Jinja2 Homepage
- Jinja2 Developer Documentation
- Jinja2 Template Documentation

**Legacy Templates**

Existing Genshi templates have been moved to the `templates_legacy` directory and will continue to be served if no file with the same name is located in `templates`. This should ensure backward compatibility until instances are able to upgrade to the new system.

The lookup path for templates is as follows. Give the template path “user/index.html”:

1. Look in the template directory of each loaded extension.
2. Look in the template_legacy directory for each extension.
3. Look in the main ckan template directory.
4. Look in the template_legacy directory.

CKAN will automatically determine the template engine to use.

**File Structure**

The file structure for the CKAN templates is pretty much the same as before with a directory per controller and individual files per action.

With Jinja2 we also have the ability to use snippets which are small fragments of HTML code that can be pulled in to any template. These are kept in a snippets directory within the same folder as the actions that are using them. More generic snippets are added to templates/snippets.

```
templates/
  base.html       # A base template with just core HTML structure
  page.html       # A base template with default page layout
  header.html     # The site header.
  footer.html     # The site footer.
  snippets/       # A folder of generic sitewide snippets
  home/
    index.html   # Template for the index action of the home controller
    snippets/    # Snippets for the home controller
  user/
    ...
templates_legacy/ # All ckan templates
```

**Using the templating system**

Jinja2 makes heavy use of template inheritance to build pages. A template for an action will tend to inherit from `page.html`:

```
{% extends "page.html" %}
```

Each parent defines a number of blocks that can be overridden to add content to the page. `page.html` defines majority of the markup for a standard page. Generally only `{% block primary_content %}` needs to be extended:

```
{% extends "page.html" %}

{% block page_content.html %}
 <h1>My page title</h1>
 <p>This content will be added to the page</p>
{% endblock %}
```

Most template pages will define enough blocks so that the extending page can customise as little or as much as required.

**Internationalisation**

See *Internationalizing strings in Jinja2 templates*.

**Conventions**

There are a few common conventions that have evolved from using the language.
Includes

**Note:** Includes should be avoided as they are not portable use `{% snippet %}` tags whenever possible.

Snippets of text that are included using `{% include %}` should be kept in a directory called `_snippets_`. This should be kept in the same directory as the code that uses it.

Generally we use the `{% snippet %}` helper in all theme files unless the parents context must absolutely be available to the snippet. In which case the usage should be clearly documented.

Snippets

**Note:** `{% snippet %}` tags should be used in favour of `h.snippet()`

Snippets are essentially middle ground between includes and macros in that they are includes that allow a specific context to be provided (includes just receive the parent context).

These should be preferred to includes at all times as they make debugging much easier.

Macros

Macros should be used very sparingly to create custom generators for very generic snippets of code. For example macros/form.html has macros for creating common form fields.

They should generally be avoided as they are hard to extend and customise.

**Templating within extensions**

When you need to add or customize a template from within an extension you need to tell CKAN that there is a template directory that it can call from. Within your `update_config` method for the extension you’ll need to add an `extra_template_paths` to the config.

**Custom Control Structures**

We’ve provided a few additional control structures to make working with the templates easier. Other helpers can still be used using the h object as before.

**ckan_extends**

```
{% ckan_extends %}
```

This works in a very similar way to `{% extend %}` however it will load the next template up in the load path with the same name.

For example if you wish to remove the breadcrumb from the user profile page in your own site. You would locate the template you wish to override.
And create a new one in your theme extension.

```python
{% ckan_extends %}

# Remove the breadcrumb #
{% block breadcrumb %}{% endblock %}
```

This will now render the current user/read page but we can override any portion that we wish to change. In this case the `breadcrumb` block.

```python
{% ckan_extends %}

{% # Remove the breadcrumb %}
{% block breadcrumb %}{% endblock %}
```

This function works recursively and so is ideal for extensions that wish to add a small snippet of functionality to the page.

**Note:** `{% ckanExtend %}` only extends templates of the same name.

### snippet

```python
{% snippet [filepath], [arg1=arg1], [arg2=arg2]... %}
```

Snippets work very much like Jinja2's `{% include %}` except that that do not inherit the parent templates context. This means that all variables must be explicitly passed in to the snippet. This makes debugging much easier.

```python
{% snippet "package/snippets/package_form.html", data=data, errors=errors %}
```

### url_for

```python
{% url_for [arg1=arg1], [arg2=arg2]... %}
```

Works exactly the same as `h.url_for()`:

```html
<a href="{{ url_for controller="home", action="index" }}">Home</a>
```

### link_for

```python
{% link_for text, [arg1=arg1], [arg2=arg2]... %}
```

Works exactly the same as `h.link_for()`:

```html
<li>{{ link_for _("Home"), controller="home", action="index" }}</li>
```
url_for_static

```{% url_for_static path %}%```

Works exactly the same as `h.url_for_static()`:

```<script src="{% url_for_static "javascript/home.js" %}"/></script>```

Form Macros

For working with forms we have provided some simple macros for generating common fields. These will be suitable for most forms but anything more complicated will require the markup to be written by hand.

The macros can be imported into the page using the `% import %` command.

```{% import 'macros/form.html' as form %}```

The following fields are provided:

**form.input()**

Creates all the markup required for an input element. Handles matching labels to inputs, error messages and other useful elements.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the form parameter.</td>
</tr>
<tr>
<td>id</td>
<td>The id to use on the input and label. Convention is to prefix with 'field-'.</td>
</tr>
<tr>
<td>label</td>
<td>The human readable label.</td>
</tr>
<tr>
<td>value</td>
<td>The value of the input.</td>
</tr>
<tr>
<td>type</td>
<td>The type of input eg. email, url, date (default: text).</td>
</tr>
<tr>
<td>error</td>
<td>A list of error strings or just true to highlight the field.</td>
</tr>
<tr>
<td>classes</td>
<td>An array of classes to apply to the control-group.</td>
</tr>
<tr>
<td>attrs</td>
<td>Dictionary of extra tag attributes</td>
</tr>
<tr>
<td>is_required</td>
<td>Boolean of whether this input is required for the form to validate</td>
</tr>
</tbody>
</table>

Examples:

```{% import 'macros/form.html' as form %}```
```{{ form.input('title', label=_('Title'), value=data.title, error=errors.title) }}```  

**form.checkbox()**

Builds a single checkbox input.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the form parameter.</td>
</tr>
<tr>
<td>id</td>
<td>The id to use on the input and label. Convention is to prefix with 'field-'.</td>
</tr>
<tr>
<td>label</td>
<td>The human readable label.</td>
</tr>
<tr>
<td>value</td>
<td>The value of the input.</td>
</tr>
<tr>
<td>checked</td>
<td>If true the checkbox will be checked</td>
</tr>
</tbody>
</table>

(continues on next page)
error - An error string for the field or just true to highlight the field.
classes - An array of classes to apply to the control-group.
attrs - Dictionary of extra tag attributes
is_required - Boolean of whether this input is required for the form to validate

Example:

{% import 'macros/form.html' as form %}
{{ form.checkbox('remember', checked=true) }}

form.select()

Creates all the markup required for a select element. Handles matching labels to inputs and error messages.

A field should be a dict with a “value” key and an optional “text” key which will be displayed to the user. 
{"value": "my-option", "text": "My Option"}. We use a dict to easily allow extension in future should extra options be required.

name - The name of the form parameter.
id - The id to use on the input and label. Convention is to prefix with 'field-'.
label - The human readable label.
options - A list/tuple of fields to be used as <options>.
selected - The value of the selected <option>.
error - A list of error strings for the field or just true to highlight the._field.
classes - An array of classes to apply to the control-group.
attrs - Dictionary of extra tag attributes
is_required - Boolean of whether this input is required for the form to validate

Examples:

{% import 'macros/form.html' as form %}
{{ form.select('year', label=_('Year'), options=[{'name':2010, 'value': 2010},{'name': 2011, 'value': 2011}], selected=2011, error=errors.year) }}

form.textarea()

Creates all the markup required for a plain textarea element. Handles matching labels to inputs, selected item and error messages.

name - The name of the form parameter.
id - The id to use on the input and label. Convention is to prefix with 'field-'.
label - The human readable label.
value - The value of the input.
placeholder - Some placeholder text.
error - A list of error strings for the field or just true to highlight the._field.
classes - An array of classes to apply to the control-group.
attrs - Dictionary of extra tag attributes
is_required - Boolean of whether this input is required for the form to validate

Examples:

{% import 'macros/form.html' as form %}
{{ form.textarea('year', placeholder='Enter your message', error=errors.year) }}
form.markdown()

Creates all the markup required for a Markdown textarea element. Handles matching labels to inputs, selected item and error messages.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the form parameter.</td>
</tr>
<tr>
<td>id</td>
<td>The id to use on the input and label. Convention is to prefix with 'field-'.</td>
</tr>
<tr>
<td>label</td>
<td>The human readable label.</td>
</tr>
<tr>
<td>value</td>
<td>The value of the input.</td>
</tr>
<tr>
<td>placeholder</td>
<td>Some placeholder text.</td>
</tr>
<tr>
<td>error</td>
<td>A list of error strings for the field or just true to highlight the field.</td>
</tr>
<tr>
<td>classes</td>
<td>An array of classes to apply to the control-group.</td>
</tr>
<tr>
<td>attrs</td>
<td>Dictionary of extra tag attributes</td>
</tr>
<tr>
<td>is_required</td>
<td>Boolean of whether this input is required for the form to validate</td>
</tr>
</tbody>
</table>

Examples:

```python
{% import 'macros/form.html' as form %}
{{ form.markdown('desc', id='field-description', label=_('Description'), value=data.desc, error=errors.desc) }}
```

form.prepend()

Creates all the markup required for an input element with a prefixed segment. These are useful for showing url slugs and other fields where the input information forms only part of the saved data.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the form parameter.</td>
</tr>
<tr>
<td>id</td>
<td>The id to use on the input and label. Convention is to prefix with 'field-'.</td>
</tr>
<tr>
<td>label</td>
<td>The human readable label.</td>
</tr>
<tr>
<td>prepend</td>
<td>The text that will be prepended before the input.</td>
</tr>
<tr>
<td>value</td>
<td>The value of the input.</td>
</tr>
<tr>
<td>placeholder</td>
<td>Some placeholder text.</td>
</tr>
<tr>
<td>error</td>
<td>A list of error strings for the field or just true to highlight the field.</td>
</tr>
<tr>
<td>classes</td>
<td>An array of classes to apply to the control-group.</td>
</tr>
<tr>
<td>attrs</td>
<td>Dictionary of extra tag attributes</td>
</tr>
<tr>
<td>is_required</td>
<td>Boolean of whether this input is required for the form to validate</td>
</tr>
</tbody>
</table>

Examples:

```python
{% import 'macros/form.html' as form %}
{{ form.prepend('slug', id='field-slug', prepend='/dataset/', label=_('Slug'), value=data.slug, error=errors.slug) }}
```
form.custom()

Creates all the markup required for a custom key/value input. These are usually used to let the user provide custom meta data. Each “field” has three inputs one for the key, one for the value and a checkbox to remove it. So the arguments for this macro are nearly all tuples containing values for the (key, value, delete) fields respectively.

- **name** - A tuple of names for the three fields.
- **id** - An id string to be used for each input.
- **label** - The human readable label for the main label.
- **values** - A tuple of values for the (key, value, delete) fields. If delete is truthy the checkbox will be checked.
- **placeholder** - A tuple of placeholder text for the (key, value) fields.
- **error** - A list of error strings for the field or just true to highlight the field.
- **classes** - An array of classes to apply to the control-group.
- **attrs** - Dictionary of extra tag attributes
- **is_required** - Boolean of whether this input is required for the form to validate

Examples:

```python
{% import 'macros/form.html' as form %}
{{ form.custom(
    names=('custom_key', 'custom_value', 'custom_deleted'),
    id='field-custom',
    label=_('Custom Field'),
    values=(extra.key, extra.value, extra.deleted),
    error=''
)}}
```

form.autoform()

Builds a form from the supplied form_info list/tuple.

- **form_info** - A list of dicts describing the form field to build.
- **data** - The form data object.
- **errors** - The form errors object.
- **error_summary** - The form errors object.

Example

```python
{% set form_info = [
    {'name': 'ckan.site_title', 'control': 'input', 'label': _('Site Title'),
     'placeholder': ''},
    {'name': 'ckan.main_css', 'control': 'select', 'options': styles, 'label': _('Style'),
     'placeholder': ''},
    {'name': 'ckan.site_description', 'control': 'input', 'label': _('Site Tag Line'),
     'placeholder': ''},
    {'name': 'ckan.site_logo', 'control': 'input', 'label': _('Site Tag Logo'),
     'placeholder': ''},
    {'name': 'ckan.site_about', 'control': 'markdown', 'label': _('About'),
     'placeholder': _('About page text')},
    {'name': 'ckan.site_intro_text', 'control': 'markdown', 'label': _('Intro Text'),
     'placeholder': _('Text on home page')},
    {'name': 'ckan.site_custom_css', 'control': 'textarea', 'label': _('Custom CSS'),
     'placeholder': _('Customisable css inserted into the page header'))
] %}
```
7.17.2 Resources

**Note:** Resources are only supported in the new Jinja2 style templates in CKAN 2.0 and above.

Resources are `.css` and `.js` files that may be included in an HTML page. Resources are included in the page by using the `{% resource %}` tag and CKAN uses Fanstatic to serve these resources.

```
{% resource 'library_name/resource_name' %}
```

Resources are grouped into libraries and the full resource name consists of `<library name>/<resource name>`. For example:

```
{% resource 'my_fanstatic_library/my_javascript_file.js' %}
```

It is important to note that these resources will be added to the page as defined by the resources, not in the location of the `{% resource %}` tag. Duplicate resources will not be added and any dependencies will be included as well as the resources, all in the correct order (see below for details).

Libraries can be added to CKAN from extensions using a helper function within the toolkit. See below.

In debug mode resources are served un-minified and unbundled (each resource is served separately). In non-debug mode the files are served minified and bundled (where allowed).

**Important:** `.js` and `.css` resources must be supplied as un-minified files. Minified files will be created. It is advised to include a `.gitignore` file to prevent minified files being added to the repository.

### Resources within extensions

To add a resource within an extension helper function `add_resource(path, name)`:

```
ckan.plugins.toolkit.add_resource('path/to/my/fanstatic/library/dir', 'my_fanstatic_library')
```

The first argument, `path`, is the path to the resource directory relative to the file calling the function. The second argument, `name` is the name of the library (to be used by templates when they want to include a resource from the library using the `{% resource %}` tag as shown above).

Resources will be created for the library for any `.js` and `.css` files found in the directory or its subfolders. The resource name being the name of the file including any path needed to get to it from the resource directory. For greater control of the creation a `resource.config` file can be created and placed in the resource directory (see below for details).

**resource.config**

This file is used to define the resources in a directory and is sub folders. Here is an example file. The general layout of the file and allowed syntax is the same as for the `.ini` config file.
# Example resource.config file

```
[main]
dont_bundle = jquery.js
force_top = html5.js
order = jquery.js jed.js

[IE conditional]
lte IE 8 = html5.js block_html5_shim
IE 7 = font-awesome/css/font-awesome-ie7.css
others = html5.js

[custom render order]
block_html5_shim = 1
html5.js = 2
select2/select2.css = 9

[inline scripts]
block_html5_shim =
  var html5 = {shivMethods: false};

[depends]
vendor = jquery.js

[groups]
vendor =
  jed.js
  html5.js
  select2/select2.js
  select2/select2.css
  bootstrap/js/bootstrap-transition.js
  bootstrap/js/bootstrap-modal.js
  bootstrap/js/bootstrap-alert.js
  bootstrap/js/bootstrap-tab.js
  bootstrap/js/bootstrap-button.js
  font-awesome/css/font-awesome-ie7.css
```

**[main]**

This can contain the following values:

**force_top**

The resources listed will be placed in the head of the page. This is only relevant to .js files which will by default will be added to the bottom of the page.

**dont_bundle**

Bundelining resources causes them to be served to the browser as a single resource to prevent multiple requests to the server. The resources listed will not be bundled. By default items will be bundled where possible. Note that .css files can only be bundled if they are in the same directory.
order
This is used to make sure that resources are created in the order specified. It should not generally be needed but is available if there are problems.

[IE conditional]
This allows IE conditionals to be wrapped around resources
eg <!--[if IE lte 8]--> <script src="my_script.js"></script> <![endif]-->
The condition is supplied followed by a list of resources that need that condition.

others
This is a special condition that means that the resource will also be available for none IE browsers.

[custom render order]
By default resources have a render order this is 10 for .css and 20 for .js resources. Sometimes we need to add resources before or after they would be included an example being the html5shim.js that needs including before .css resources. By providing a custom render order for the resource it’s placement can be altered. Lower numbered resources are rendered earlier. Note that resources rendered in the head will still be placed before ones rendered in the body.

[inline scripts]
It is possible to define inline scripts in the resource.config file this can be helpful in some situations but is probably best avoided if possible.

[depends]
Some times one resource depends on another eg many scripts need jquery.js included in the page before them. External resource libraries will automatically depend on the core CKAN JavaScript modules so do not need to specify this.

[groups]
Groups of resources can be specified this allows the group to be included by just using it’s name rather than having to specify each resource individuality when requesting them. The order that items are added to a group will be used to order the resources when added to the page but other factors such as dependencies, custom render order and resource type can affect the final order used.
Groups can be referred to in many places in the resource.config file eg. [depends]

7.17.3 Creating a new template
This is a brief tutorial covering the basics of building a common template.
Extending a base template

Firstly we need to extend a parent template to provide us with some basic page structure. This can be any other HTML page however the most common one is page.html which provides the full CKAN theme including header and footer.

```
{% extends "page.html" %}
```

The page.html template provides numerous blocks that can be extended. It’s worth spending a few minutes getting familiar with what’s available. The most common blocks that we’ll be using are those ending with “content”.

- **primary_content**: The main content area of the page.
- **secondary_content**: The secondary content (sidebar) of the page.
- **breadcrumb_content**: The contents of the breadcrumb navigation.
- **actions_content**: The content of the actions bar to the left of the breadcrumb.

Primary Content

For now we’ll add some content to the main content area of the page.

```
{% block primary_content %}
  {{ super() }}

  {% block my_content %}
    <h2>{{ _('This is my content heading') }}</h2>
    <p>{{ _('This is my content') }}</p>
  {% endblock %}

{% endblock %}
```

Notice we’ve wrapped our own content in a block. This allows other templates to extend and possibly override this one and is extremely useful for making a them more customisable.

Secondary Content

Secondary content usually compromises of reusable modules which are pulled in as snippets. Snippets are also very useful for keeping the templates clean and allowing theme extensions to override them.

```
{% block primary_content %}
  {{ super() }}

  {% block my_sidebar_module %}
    {% snippet "snippets/my-sidebar-module.html" %}
  {% endblock %}

{% endblock %}
```

Breadcrumb and Actions

There is a consistent breadcrumb running through all the pages and often it is useful to provide additional actions that a related to the page.
Scripts and Stylesheets

Currently scripts and stylesheets can be added by extending the styles and scripts blocks. This is soon to be replaced with the `{% resource %}` tag which manages script loading for us.

```
{% block styles %}
{{ super() }}
<link rel="stylesheet" href="{{ url_for_static "my-style.css" }}" />
{% endblock %}

{% block scripts %}
{{ super() }}
<script src="{{ url_for_static "my-script.js" }}"></script>
{% endblock %}
```

Summary

And that’s about all there is to it be sure to check out base.html and page.html to see all the tags available for extension.

7.17.4 Template Blocks

These blocks can be extended by child templates to replace or extend common CKAN functionality.

Usage

There are currently two base templates base.html which provides the bare HTML structure such as title, head and body tags as well as hooks for adding links, stylesheets and scripts. page.html defines the content structure and is the template that you’ll likely want to use.

To extend a template simply create a new template file and call `{% extend %}` then define the blocks that you wish to override.

7.17.5 Blocks in page.html

`page.html` extends the “page” block in `base.html` and provides the basic page structure for primary and secondary content.
header

Override the header on a page by page basis by extending this block. If making site wide header changes it is preferable to override the header.html file:

{% block header %}
    {% include "custom_header.html" %}
{% endblock %}

content

The content block allows you to replace the entire content section of the page with your own markup if needed:

{% block content %}
    <div class="custom-content">
        {% block custom_block %}{% endblock %}
    </div>
{% endblock %}

toolbar

The toolbar is for content to be added at the top of the page such as the breadcrumb navigation. You can remove/replace this by extending this block:

{% block toolbar %}{% endblock %}

breadcrumb

Add a breadcrumb to the page by extending this element:

{% block breadcrumb %}
    {% include "breadcrumb.html" %}
{% endblock %}

actions

Add actions to the page by extending this element:

{% block actions %}
    <a class="btn" href="{{ save_url }}">Save</a>
{% endblock %}

primary

This block can be used to remove the entire primary content element:

{% block primary %}{% endblock %}
**primary_content**

The primary_content block can be used to add content to the page. This is the main block that is likely to be used within a template:

```html
{% block primary_content %}
<h1>My page content</h1>
<p>Some content for the page</p>
{% endblock %}
```

**secondary**

This block can be used to remove the entire secondary content element:

```html
{% block secondary %}{% endblock %}
```

**secondary_content**

The secondary_content block can be used to add content to the sidebar of the page. This is the main block that is likely to be used within a template:

```html
{% block secondary_content %}
<h2>A sidebar item</h2>
<p>Some content for the item</p>
{% endblock %}
```

**footer**

Override the footer on a page by page basis by extending this block:

```html
{% block footer %}
{% include "custom_footer.html" %}
{% endblock %}
```

If making site wide header changes it is preferable to override the footer.html. Adding scripts should use the “scripts” block instead.

### 7.17.6 Blocks in base.html

**doctype**

Allows the DOCTYPE to be set on a page by page basis:

```html
{% block doctype %}
<!DOCTYPE html>{% endblock %}
```

**htmltag**

Allows custom attributes to be added to the <html> tag:
headtag

Allows custom attributes to be added to the <head> tag:

```html
<head data-tag="No idea what you'd add here"></head>
```

bodytag

Allows custom attributes to be added to the <body> tag:

```html
<body class="full-page"></body>
```

meta

Add custom meta tags to the page. Call `super()` to get the default tags such as charset, viewport and generator:

```html
{{ super() }}
<meta name="author" value="Joe Bloggs" />
<meta name="description" value="My website description" />
```

title

Add a custom title to the page by extending the title block. Call `super()` to get the default page title:

```html
My Subtitle - {{ super() }}
```

links

The links block allows you to add additional content before the stylesheets such as rss feeds and favicons in the same way as the meta block:

```html
<meta rel="shortcut icon" href="custom_icon.png" />
```

styles

The styles block allows you to add additional stylesheets to the page in the same way as the meta block. Use `super()` to include the default stylesheets before or after your own:

```html
{{ super() }}
<link rel="stylesheet" href="/base/css/custom.css" />
```
The page block allows you to add content to the page. Most of the time it is recommended that you extend one of the page.html templates in order to get the site header and footer. If you need a clean page then this is the block to use:

{% block page %}
  <div>Some other page content</div>
{% endblock %}

The scripts block allows you to add additional scripts to the page. Use the super() function to load the default scripts before/after your own:

{% block scripts %}
  {{ super() }}
  <script src="/base/js/custom.js"></script>
{% endblock %}

### 7.17.7 Building a JavaScript Module

CKAN makes heavy use of modules to add additional functionality to the page. Essentially all a module consists of is an object with an .initialize() and .teardown() method.

Here we will go through the basic functionality of building a simple module that sends a “favourite” request to the server when the user clicks a button.

#### HTML

The idea behind modules is that the element should already be in the document when the page loads. For example our favourite button will work just fine without our module JavaScript loaded.

```
<form action="/favourite" method="post" data-module="favorite">
  <button class="btn" name="package" value="101">Submit</button>
</form>
```

Here it’s the data-module="favorite" that tells the CKAN module loader to create a new instance for this element.

#### JavaScript

Modules reside in the javascript/modules directory and should share the same name as the module. We use hyphens to delimit spaces in both filenames and modules.

```
/javascript/modules/favorite.js
```

A module can be created by calling ckan.module():

```
ckan.module('favorite', function (jQuery) {
    return {
    };
});
```
We pass in the module name and a factory function that should return our module object. This factory gets passed a local jQuery object and a translation object.

Note: In order to include a module for page render inclusion within an extension it is recommended that you use `{% resource %}` within your templates. See the Resource Documentation

**Initialisation**

Once ckan has found an element on the page it creates a new instance of your module and if present calls the `.initialize()` method.

```javascript
ckan.module('favorite', function (jQuery) {
    return {
        initialize: function () {
            console.log('I've been called for element: %o', this.el);
        }
    };
});
```

Here we can set up event listeners and other setup functions.

```javascript
initialize: function () {
    // Grab our button and assign it to a property of our module.
    this.button = this.$('button');

    // Watch for our favourite button to be clicked.
    this.button.on('submit', jQuery.proxy(this._onClick, this));
},
_onClick: function (event) {
```

**Event Handling**

Now we create our click handler for the button:

```javascript
_onClick: function (event) {
    event.preventDefault();
    this.favorite();
}
```

And this calls a `.favorite()` method. It’s generally best not to do too much in event handlers it means that you can’t use the same functionality elsewhere.

```javascript
favorite: function () {
    // The client on the sandbox should always be used to talk to the api.
    this.sandbox.client.favoriteDataset(this.button.val());
}
```

**Internationalisation**

See *Internationalizing strings in JavaScript code.*
Notifications

This submits the dataset to the API but ideally we want to tell the user what we’re doing.

```
favorite: function () {
    this.button.text('Loading');
    // The client on the sandbox should always be used to talk to the api.
    var request = this.sandbox.client.favoriteDataset(this.button.val());
    request.done(jQuery.proxy(this._onSuccess, this));
},
_onSuccess: function () {
    // Notify allows global messages to be displayed to the user.
    this.sandbox.notify('Done', 'success');
}
```

Options

Displaying an id to the user isn’t very friendly. We can use the `data-module` attributes to pass options through to the module.

```
<form action="/favourite" method="post" data-module="favorite" data-module-dataset="my dataset">
```

This will override the defaults in the options object.

```
ckan.module('favorite', function (jQuery) {
    return {
        options: {
            dataset: ''
        }
    }
},
initialize: function () {
    console.log('this dataset is: %s', this.options.dataset);
    //=> "this dataset is: my dataset"
}
});
```

Error handling

When ever we make an Ajax request we want to make sure that we notify the user if the request fails. Again we can use `this.sandbox.notify()` to do this.

```
favorite: function () {
    // The client on the sandbox should always be used to talk to the api.
    var request = this.sandbox.client.favoriteDataset(this.button.val());
    request.done(jQuery.proxy(this._onSuccess, this));
    request.fail(jQuery.proxy(this._onError, this));
},
_onError: function () {
    // Notify allows global messages to be displayed to the user.
    this.sandbox.notify('An error occurred!', 'error');
}
```
Module Scope

You may have noticed we keep making calls to `jQuery.proxy()` within these methods. This is to ensure that this when the callback is called is the module it belongs to.

We have a shortcut method called `jQuery.proxyAll()` that can be used in the `.initialize()` method to do all the binding at once. It can accept method names or simply a regexp.

```javascript
initialize: function () {
  jQuery.proxyAll(this, '_onSuccess);

  // Same as:
  this._onSuccess = jQuery.proxy(this, '_onSuccess);

  // Even better do all methods starting with _on at once.
  jQuery.proxyAll(this, /_on/);
}
```

Publish/Subscribe

Sometimes we want modules to be able to talk to each other in order to keep the page state up to date. The sandbox has the `.publish()` and `.subscribe()` methods for just this cause.

For example say we had a counter up in the header that showed how many favourite datasets the user had. This would be incorrect when the user clicked the ajax button. We can publish an event when the favorite button is successful.

```javascript
_onSuccess: function () {
  // Notify allows global messages to be displayed to the user.
  this.sandbox.notify(message, 'success');

  // Tell other modules about this event.
  this.sandbox.publish('favorite', this.button.val());
}
```

Now in our other module ‘user-favorite-counter’ we can listen for this.

```javascript
ckan.module('user-favorite-counter', function (jQuery) {
  return {
    initialize: function () {
      jQuery.proxyAll(this, /_on/);
      this.sandbox.subscribe('favorite', this._onFavorite);
    },
    teardown: function () {
      // We must always unsubscribe on teardown to prevent memory leaks.
      this.sandbox.unsubscribe('favorite', this._onFavorite);
    },
    incrementCounter: function () {
      var count = this.el.text() + 1;
      this.el.text(count);
    },
    _onFavorite: function (id) {
      this.incrementCounter();
    }
  };
});
```
**Unit Tests**

Every module has unit tests. These use Mocha, Chai and Sinon to assert the expected functionality of the module.

### 7.17.8 Install frontend dependencies

The front end stylesheets are written using Less (this depends on node.js being installed on the system).

Instructions for installing Node.js can be found on the Node.js website. Please check the ones relevant to your own distribution.

On Ubuntu, run the following to install Node.js official repository and the node package:

```bash
curl -sL https://deb.nodesource.com/setup_4.x | sudo -E bash -
sudo apt-get install -y nodejs
```

**Note:** If you use the package on the default Ubuntu repositories (eg `sudo apt-get install nodejs`), the node binary will be called `nodejs`. This will prevent the CKAN less script to work properly, so you will need to create a link to make it work:

```bash
ln -s /usr/bin/nodejs /usr/bin/node
```

Also npm (the Node.js package manager) needs to be installed separately:

```bash
sudo apt-get install npm
```

For more information, refer to the Node.js instructions.

Less can then be installed via the node package manager (npm). We also use nodewatch to make our Less compiler a watcher style script.

`cd` into the CKAN source folder (eg `/usr/lib/ckan/default/src/ckan`) and run:

```bash
$ npm install less@1.7.5 nodewatch
```

You may need to use `sudo` depending on your CKAN install type.

### 7.17.9 File structure

All front-end files to be served via a web server are located in the public directory (in the case of the new CKAN base theme it’s public/base).
jquery.js
jquery.plugin.js
underscore.js
bootstrap.css
...
test/
  index.html
  spec/
    main.spec.js
    utils.spec.js
  vendor/
    mocha.js
    mocha.css
    chai.js
...

All files and directories should be lowercase with hyphens used to separate words.

css  Should contain any site specific CSS files including compiled production builds generated by Less.

less  Should contain all the less files for the site. Additional vendor styles should be added to the vendor directory and included in main.less.

javascript  Should contain all website files. These can be structured appropriately. It is recommended that main.js be used as the bootstrap filename that sets up the page.

vendor  Should contain all external dependencies. These should not contain version numbers in the filename. This information should be available in the header comment of the file. Library plugins should be prefixed with the library name. If a dependency has many files (such as bootstrap) then the entire directory should be included as distributed by the maintainer.

test  Contains the test runner index.html. vendor contains all test dependencies and libraries. spec contains the actual test files. Each test file should be the filename with .spec appended.

7.17.10 Stylesheets

Because all the stylesheets are using Less we need to compile them before beginning development by running:

```
$ ./bin/less
```

This will watch for changes to all of the less files and automatically rebuild the CSS for you. To quit the script press ctrl-c. There is also --production flag for compiling the production main.css.

There are many Less files which attempt to group the styles in useful groups. The main two are:

main.less:  This contains all the styles for the website including dependancies and local styles. The only files that are excluded here are those that are conditionally loaded such as IE only CSS and large external apps (like recline) that only appear on a single page.

ckan.less:  This includes all the local ckan stylesheets.

**Note:** Whenever a CSS change effects main.less it’s important than after the merge into master that a $ ./bin/less --production should be run and commited.

There is a basic pattern primer available at: [http://localhost:5000/testing/primer/](http://localhost:5000/testing/primer/) that shows all the main page elements that make up the CKAN core interface.
### 7.17.11 JavaScript

The core of the CKAN JavaScript is split up into three areas.

- **Core** (such as i18n, pub/sub and API clients)
- **Modules** (small HTML components or widgets)
- **jQuery Plugins** (very small reusable components)

#### Core

Everything in the CKAN application lives on the `ckan` namespace. Currently there are four main components that make up the core.

- **Modules**
- **Publisher/Subscriber**
- **Client**
- **i18n/Jed**

#### Modules

Modules are the core of the CKAN website, every component that is interactive on the page should be a module. These are then initialized by including a `data-module` attribute on an element on the page. For example:

```html
<select name="format" data-module="autocomplete"></select>
```

The idea is to create small isolated components that can easily be tested. They should ideally not use any global objects, all functionality should be provided to them via a “sandbox” object.

There is a global factory that can be used to create new modules and jQuery and Localisation methods are available via `this.sandbox.jQuery` and `this.sandbox.translate()` respectively. To save typing these two common objects we can take advantage of JavaScript closures and use an alternative module syntax that accepts a factory function.

```javascript
ckan.module('my-module', function (jQuery) {
  return {
    initialize: function () {
      // Called when a module is created.
      // jQuery and translate are available here.
    },
    teardown: function () {
      // Called before a module is removed from the page.
    }
  }
});
```

**Note:** A guide on creating your own modules is located in the *Building a JavaScript Module* guide.
Publisher/subscriber

There is a simple pub/sub module included under ckan.pubsub it’s methods are available to modules via this.sandbox.publish/subscribe/unsubscribe. This can be used to publish messages between modules.

Modules should use the publish/subscribe methods to talk to each other and allow different areas of the UI to update where relevant.

```javascript
ckan.module('language-picker', function ($, module) {
    return {
        initialize: function () {
            var sandbox = this.sandbox;
            this.el.on('change', function () {
                sandbox.publish('change:lang', this.selected);
            });
        }
    }
});

ckan.module('language-notifier', function ($, module) {
    return {
        initialize: function () {
            this.sandbox.subscribe('change:lang', function (lang) {
                alert('language is now ' + lang);
            });
        }
    }
});
```

Client

Ideally no module should use jQuery.ajax() to make XHR requests to the CKAN API, all functionality should be provided via the client object.

```javascript
ckan.module('my-module', function ($, module) {
    return {
        initialize: function () {
            this.sandbox.client.getCompletions(this.options.completionsUrl);
        }
    }
});
```

Internationalization

See *Internationalizing strings in JavaScript code*.

Life cycle

CKAN modules are intialised on dom ready. The ckan.module.initialize() will look for all elements on the page with a data-module attribute and attempt to create an instance.

```html
<select name="format" data-module="autocomplete" data-module-key="id"></select>
```
The module will be created with the element, any options object extracted from data-module- attributes and a new sandbox instance. Once created the modules initialize() method will be called allowing the module to set themselves up. Modules should also provide a teardown() method this isn’t used at the moment except in the unit tests to restore state but may become useful in the future.

jQuery plugins

Any functionality that is not directly related to ckan should be packaged up in a jQuery plug-in if possible. This keeps the modules containing only ckan specific code and allows plug-ins to be reused on other sites. Examples of these are jQuery.fn.slug(), jQuery.fn.slugPreview() and jQuery.proxyAll().

Unit tests

There is currently a test suite available at: http://localhost:5000/base/test/index.html

Every core component, module and plugin should have a set of unit tests. Tests can be filtered using the grep={regexp} query string parameter.

The libraries used for the tests are as follows.

- **Mocha**: A test runner using a BDD style syntax.
- **Chai**: An assertion library (we use the assert style).
- **Sinon**: A stubbing library, can stub objects, timers and ajax requests.

Each file has a description block for it’s top level object and then within that a nested description for each method that is to be tested:

```javascript
describe('ckan.module.MyModule()', function () {
  describe('.initialize()', function () {
    it('should do something...', function () {
      // assertions.
    });
  });

  describe('.myMethod(arg1, arg2, arg3)', function () {
    // assertions.
  });
});
```

The `.beforeEach()` and `.afterEach()` callbacks can be used to setup objects for testing (all blocks share the same scope so test variables can be attached):

```javascript
describe('ckan.module.MyModule()', function () {
  // Pull the class out of the registry.
  var MyModule = ckan.module.registry['my-module'];

  beforeEach(function () {
    // Create a test element.
    this.el = jQuery('<div />');

    // Create a test sandbox.
    this.sandbox = ckan.sandbox();

    // Call initialize on the module.
    MyModule.initialize();

    // Assert the expected state.
    expect(this.el).to.have.property('data-test').equal('true');
  });
});
```

(continues on next page)
Templates can also be loaded using the .loadFixtures() method that is available in all test contexts. Tests can be made asynchronous by setting a done argument in the callback (Mocha checks the arity of the functions):

```javascript
describe('ckan.module.MyModule()', function () {

  before(function (done) {
    // Load the template once.
    this.loadFixture('my-template.html', function (html) {
      this.template = html;
      done();
    });
  });

  beforeEach(function () {
    // Assign the template to the module each time.
    this.el = this.fixture.html(this.template).children();
  });

  afterEach(function () {
    // Clean up.
    this.module.teardown();
  });

  // Create a test module.
  this.module = new MyModule(this.el, {}, this.sandbox);
});
```

## 7.18 Database migrations

When changes are made to the model classes in ckan.model that alter CKAN’s database schema, a migration script has to be added to migrate old CKAN databases to the new database schema when they upgrade their copies of CKAN. These migration scripts are kept in ckan.migration.versions.

When you upgrade a CKAN instance, as part of the upgrade process you run any necessary migration scripts with the `paster db upgrade` command.

A migration script should be checked into CKAN at the same time as the model changes it is related to. Before pushing the changes, ensure the tests pass when running against the migrated model, which requires the `--ckan-migration` setting.

To create a new migration script, create a python file in ckan/migration/versions/ and name it with a prefix numbered one higher than the previous one and some words describing the change.

You need to use the special engine provided by the SQLAlchemy Migrate. Here is the standard header for your migrate script:

```python
from sqlalchemy import *
from migrate import *
```

The migration operations go in the upgrade function:

```python
def upgrade(migrate_engine):
    metadata = MetaData()
    metadata.bind = migrate_engine
```

The following process should be followed when doing a migration. This process is here to make the process easier and to validate if any mistakes have been made:

1. Get a dump of the database schema before you add your new migrate scripts.

```
paster --plugin=ckan db clean --config={.ini file}
paster --plugin=ckan db upgrade --config={.ini file}
pg_dump -h host -s -f old.sql dbname
```

2. Get a dump of the database as you have specified it in the model.

```
paster --plugin=ckan db clean --config={.ini file}
#this makes the database as defined in the model
paster --plugin=ckan db create-from-model -config={.ini file}
pg_dump -h host -s -f new.sql dbname
```

3. Get apgdiff (apt-get it). It produces sql it thinks that you need to run on the database in order to get it to the updated schema.

```
apgdiff old.sql new.sql > upgrade.diff
```

(or if you don’t want to install java use http://apgdiff.startnet.biz/diff_online.php)

4. The upgrade.diff file created will have all the changes needed in sql. Delete the drop index lines as they are not created in the model.

5. Put the resulting sql in your migrate script, e.g.

```
migrate_engine.execute('''update table .........; update table ....''')
```

6. Do a dump again, then a diff again to see if the the only thing left are drop index statements.

7. run nosetests with --ckan-migration flag.

It’s that simple. Well almost.

- If you are doing any table/field renaming adding that to your new migrate script first and use this as a base for your diff (i.e add a migrate script with these renaming before 1). This way the resulting sql won’t try to drop and recreate the field/table!
- It sometimes drops the foreign key constraints in the wrong order causing an error so you may need to rearrange the order in the resulting upgrade.diff.
- If you need to do any data transfer in the migrations then do it between the dropping of the constraints and adding of new ones.
- May need to add some tests if you are doing data migrations.

An example of a script doing it this way is 034_resource_group_table.py. This script copies the definitions of the original tables in order to do the renaming the tables/fields.

In order to do some basic data migration testing extra assertions should be added to the migration script. Examples of this can also be found in 034_resource_group_table.py for example.

This statement is run at the top of the migration script to get the count of rows:

```
package_count = migrate_engine.execute('''select count(*) from package''').first()[0]
```

And the following is run after to make sure that row count is the same:
resource_group_after = migrate_engine.execute('''select count(*) from resource_group''').first()[0]
assert resource_group_after == package_count

7.19 Upgrading CKAN’s dependencies

The Python modules that CKAN depends on are pinned to specific versions, so we can guarantee that whenever anyone installs CKAN, they’ll always get the same versions of the Python modules in their virtual environment.

Our dependencies are defined in three files:

requirements.in  This file is only used to create a new version of the requirements.txt file when upgrading the dependencies. Contains our direct dependencies only (not dependencies of dependencies) with loosely defined versions. For example, python-dateutil>=1.5.0,<2.0.0.

requirements.txt  This is the file that people actually use to install CKAN’s dependencies into their virtualenvs. It contains every dependency, including dependencies of dependencies, each pinned to a specific version. For example, simplejson==3.3.1.

dev-requirements.txt  Contains those dependencies only needed by developers, not needed for production sites. These are pinned to a specific version. For example, factory-boy==2.1.1.

We haven’t created a dev-requirements.in file because we have too few dev dependencies, we don’t update them often, and none of them have a known incompatible version.

7.19.1 Steps to upgrade

These steps will upgrade all of CKAN’s dependencies to the latest versions that work with CKAN:

1. Create a new virtualenv: virtualenv --no-site-packages upgrading
2. Install the requirements with unpinned versions: pip install -r requirements.in
3. Save the new dependencies versions: pip freeze > requirements.txt. We have to do this before installing the other dependencies so we get only what was in requirements.in
4. Install CKAN: python setup.py develop
5. Install the development dependencies: pip install -r dev-requirements.txt
6. Run the tests to make sure everything still works (see Testing CKAN).

   • If not, try to fix the problem. If it’s too complicated, pinpoint which dependency’s version broke our tests, find an older version that still works, and add it to requirements.in (i.e., if python-dateutil 2.0.0 broke CKAN, you’d add python-dateutil>=1.5.0,<2.0.0). Go back to step 1.

7. Navigate a bit on CKAN to make sure the tests didn’t miss anything. Review the dependencies changes and their changelogs. If everything seems fine, go ahead and make a pull request (see Making a pull request).

7.20 Doing a CKAN release

This section documents the steps followed by the development team to do a new CKAN release.

See also:

Upgrading CKAN  An overview of the different kinds of CKAN release, and the process for upgrading a CKAN site to a new version.
7.20.1 Process overview

Changed in version 2.6.

The process of a new release starts with the creation of a new release development branch. A release development branch is the one that will be stabilized and eventually become the actual released version. Release branches are always named dev-vM.m, after the major and minor versions they include. Major and minor versions are always branched from master. When the release is actually published a patch version number is added and the release is tagged in the form ckan-M.m.p. All backports are cherry-picked on the dev-vM.m branch.

Additionally, the release-vM.m-latest branches always contain the latest published release for that version (eg 2.6.1 on the example above).

Note: Prior to CKAN 2.6, release branches were named release-vM.m.p, after the major, minor and patch versions they included, and patch releases were always branched from the most recent tip of the previous patch release branch (tags were created with the same convention). Starting from CKAN 2.6, the convention is the one described above.

Once a release branch has been created there is generally a three-four week period until the actual release. During this period the branch is tested and fixes cherry-picked. The whole process is described in the following sections.

7.20.2 Doing the beta release

Beta releases are branched off a certain point in master and will eventually become stable releases.

Turn this file into a github issue with a checklist using this command:

```
echo 'Full instructions here: https://github.com/ckan/ckan/blob/master/doc/contributing/release-process.rst'; egrep "'\$(\#\.|Doing|Leading|Preparing)' doc/contributing/release-process.rst | sed "'s/\([^\#]\)/\n\1/g' | sed 's/\#\s\/* \[ /g' | sed 's/\[/./g'
```

1. Create a new release branch:

```
git checkout -b dev-v2.7
```

Update ckan/__init__.py to change the version number to the new version with a b after it, e.g. 2.7.0b (Make sure to include 0 as the patch version number). Commit the change and push the new branch to GitHub:

```
git commit -am "Update version number"
git push origin dev-v2.7
```
You will probably need to update the same file on master to increase the version number, in this case ending with an a (for alpha).

During the beta process, all changes to the release branch must be cherry-picked from master (or merged from special branches based on the release branch if the original branch was not compatible).

As in the master branch, if some commits involving CSS changes are cherry-picked from master, the less compiling command needs to be run on the release branch. This will update the main.css file:

```
./bin/less --production
git commit -am "Rebuild CSS"
git push
```

There will be a final front-end build before the actual release.

2. Update beta.ckan.org to run new branch.

The beta staging site (http://beta.ckan.org, currently on s084) must be set to track the latest beta release branch to allow user testing. This site is automatically updated nightly.

Check the message on the front page reflects the current version. Edit it as a syadmin here: http://beta.ckan.org/ckan-admin/config

3. Announce the branch and ask for help testing on beta.ckan.org on ckan-dev.

4. Create the documentation branch from the release branch. This branch should be named just with the minor version and nothing else (eg 2.7, 2.8, etc). We will use this branch to build the documentation in Read the Docs on all patch releases for this version.

5. Make latest translation strings available on Transifex.

During beta, a translation freeze is in place (ie no changes to the translatable strings are allowed). Strings need to be extracted and uploaded to Transifex:

(a) Install the Babel and Transifex libraries if necessary:

```
pip install --upgrade Babel
pip install transifex-client
```

(b) Create a ~/.transifexrc file if necessary with your login details (token should be left blank):

```
[https://www.transifex.com]
hostname = https://www.transifex.com
username = <username>
password = <password>
token =
```

(c) Extract new strings from the CKAN source code into the ckan.pot file. The pot file is a text file that contains the original, untranslated strings extracted from the CKAN source code.:

```
python setup.py extract_messages
```

The po files are text files, one for each language CKAN is translated to, that contain the translated strings next to the originals. Translators edit the po files (on Transifex) to update the translations. We never edit the po files locally.

(c) Get the latest translations (of the previous CKAN release) from Transifex, in case any have changed since:

```
tx pull --all --minimum-perc=5 --force
```

(This ignores any language files which less than 5% translation - which is the bare minimum we require)
(e) Update the `ckan.po` files with the new strings from the `ckan.pot` file:

```
python setup.py update_catalog --no-fuzzy-matching
```

Any new or updated strings from the CKAN source code will get into the po files, and any strings in the po files that no longer exist in the source code will be deleted (along with their translations).

We use the `--no-fuzzy-matching` option because fuzzy matching often causes problems with Babel and Transifex.

If you get this error for a new translation:

```
babel.core.UnknownLocaleError: unknown locale ‘crh’
```

then it’s Transifex appears to know about new languages before Babel does. Just delete that translation locally - it may be ok with a newer Babel in later CKAN releases.

(f) Run msgfmt checks:

```
find ckan/i18n/ -name "*.po"| xargs -n 1 msgfmt -c
```

You must correct any errors or you will not be able to send these to Transifex.

A common problem is that Transifex adds to the end of a po file as comments any extra strings it has, but msgfmt doesn’t understand them. Just delete these lines.

(g) Run our script that checks for mistakes in the ckan.po files:

```
paster check-po-files ckan/i18n/*/LC_MESSAGES/ckan.po
```

If the script finds any mistakes then at some point before release you will need to correct them, but it doesn’t need to be done now, since the priority is to announce the call for translations.

When it is done, you must do the correction on Transifex and then run the tx pull command again, don’t edit the files directly. Repeat until the script finds no mistakes.

(h) Edit `.tx/config`, on line 4 to set the Transifex ‘resource’ to the new major release name (if different), using dashes instead of dots. For instance v2.4.0, v2.4.1 and v2.4.2 all share: `[ckan.2-4]`.

(i) Create a new resource in the CKAN project on Transifex by pushing the new pot and po files:

```
tx push --source --translations --force
```

Because it reads the new version number in the `.tx/config` file, tx will create a new resource on Transifex rather than updating an existing resource (updating an existing resource, especially with the `--force` option, can result in translations being deleted from Transifex).

If you get a ‘msgfmt’ error, go back to the step where msgfmt is run.

(j) On Transifex give the new resource a more friendly name. Go to the resource e.g. https://www.transifex.com/okfn/ckan/2-5/ and the settings are accessed from the triple dot icon “…”. Keep the slug like “2-4”, but change the name to be like “CKAN 2.5”.

(k) Update the `ckan.mo` files by compiling the po files:

```
python setup.py compile_catalog
```

The mo files are the files that CKAN actually reads when displaying strings to the user.

(l) Commit all the above changes to git and push them to GitHub:
6. Send an announcement email with a call for translations.

Send an email to the ckan-dev list, tweet from @CKANproject and send a transifex announcement from: https://www.transifex.com/okfn/ckan/announcements/. Make sure to post a link to the correct Transifex resource (like this one) and tell users that they can register on Transifex to contribute. Give a deadline in two weeks time.

7. Create deb packages.

Ideally do this once a week. Create the deb package with the latest release branch, using betaX iterations. Deb packages are built using Ansible scripts located at the following repo:

https://github.com/ckan/ckan-packaging

The repository contains further instructions on how to run the scripts, butessentially you need to generate the packages (one for precise and one for trusty) on your local machine and upload them to the Amazon S3 bucket.

To generate the packages, run:

```bash
./ckan-package -v 2.x.y -i betaX
```

To upload the files to the S3 bucket, you will need the relevant credentials and to install the Amazon AWS command line interface.

Make sure to upload them to the build folder, so they are not mistaken by the stable ones:

```bash
aws s3 cp python-ckan_2.5.0-precisebeta1_amd64.deb s3://packaging.ckan.org/build/ python-ckan_2.5.0-precisebeta1_amd64.deb
```

Now the .deb files are available at http://packaging.ckan.org/build/ invite people on ckan-dev to test them.

### 7.20.3 Leading up to the release

1. Update the CHANGELOG.txt with the new version changes.

   • Add the release date next to the version number
   
   • Add the following notices at the top of the release, reflecting whether updates in requirements, database or Solr schema are required or not:

   ```
   Note: This version requires a requirements upgrade on source installations
   Note: This version requires a database upgrade
   Note: This version does not require a Solr schema upgrade
   ```

   • Check the issue numbers on the commit messages for information about the changes. The following gist has a script that uses the GitHub API to aid in getting the merged issues between releases:

   https://gist.github.com/amercader/4ec55774b9a625e815bf

   But dread found changed the first step slightly to get it to work:

   ```bash
   git log --pretty=format:%s --reverse --no-merges release-v2.4.2...release-v2.5.0 -- | grep -Pzo "^[\#\K[0-9]+" | sort -u -n > issues_2.5.txt
   ```

2. A week before the translations will be closed send a reminder email.
3. Once the translations are closed, sync them from Transifex.

Pull the updated strings from Transifex:

```
    tx pull --all --minimum-perc=5 --force
```

Check and compile them as before:

```
    paster check-po-files ckan/i18n/*/LC_MESSAGES/ckan.po
    python setup.py compile_catalog
```

The compilation shows the translation percentage. Compare this with the new languages directories added to ckan/i18n:

```
    git status
```

`git add` any new ones. (If all is well, you won’t see any that are under 5% translated.)

Now push:

```
    git commit -am "Update translations from Transifex"
    git push
```

4. A week before the actual release, announce the upcoming release(s).

Send an email to the ckan-announce mailing list, so CKAN instance maintainers can be aware of the upcoming releases. List any patch releases that will be also available. Here’s an example email.

### 7.20.4 Doing the final release

Once the release branch has been thoroughly tested and is stable we can do a release.

1. Run the most thorough tests:

```
    nosetests ckan/tests --ckan --ckan-migration --with-pylons=test-core.ini
```

2. Do a final build of the front-end, add the generated files to the repo and commit the changes:

```
    paster front-end-build
    git add ckan ckanext
    git commit -am "Rebuild front-end"
```

3. Review the CHANGELOG to check it is complete.

4. Check that the docs compile correctly:

```
    rm build/sphinx -rf
    python setup.py build_sphinx
```

5. Remove the beta letter in the version number.

The version number is in `ckan/__init__.py` (eg 2.5.0b -> 2.5.0) and commit the change:

```
    git commit -am "Update version number for release X.Y.Z"
```

6. Tag the repository with the version number.

Make sure to push it to GitHub afterwards:
7. Create and deploy the final deb package.
   Move it to the root of the publicly accessible folder of the packaging server from the /build folder.
   Make sure to rename it so it follows the deb packages name convention:
   
   ```
   python-ckan_Major.minor_amd64.deb
   ```
   
   Note that we drop any patch version or iteration from the package name.

8. Upload the release to PyPI:
   
   ```
   python setup.py sdist upload
   ```
   
   You will need a PyPI account with admin permissions on the ckan package, and your credentials should be defined on a ~/.pypirc file such as:
   
   ```
   [distutils]
   index-servers =
   pypi
   
   [pypi]
   username: <user-name>
   password: <password>
   ```
   
   For more info, see: here
   
   If running in Vagrant you may get error: Operation not permitted due to failure to create a hard link. The solution is to add a line at the top of setup.py:
   
   ```
   # Avoid problem releasing to pypi from vagrant
   import os
   if os.environ.get('USER', '') == 'vagrant':
     del os.link
   ```
   
   as described here: https://stackoverflow.com/questions/7719380/python-setup-py-sdist-error-operation-not-permitted
   
   If you upload a bad package, then you can remove it from PyPI however you must use a new version number next time.

9. Enable the new version of the docs on Read the Docs.
   (You will need an admin account.)
   
   (a) Make sure the documentation branch is up to date with the latest changes in the corresponding dev-vX.Y branch.
   
   (b) If this is the first time a minor version is released, go to the Read The Docs versions page and make the relevant release ‘active’ (make sure to use the documentation branch, ie X.Y, not the development branch, ie dev-vX.Y).
   
   (c) If it is the latest stable release, set it to be the Default Version and check it is displayed on http://docs.ckan.org.

10. Write a CKAN blog post and announce it to ckan-announce & ckan-dev & twitter.
   CKAN blog here: <http://ckan.org/wp-admin>  
   
   • Example blog
11. Cherry-pick the i18n changes from the release branch onto master.

We don’t generally merge or cherry-pick release branches into master, but the files in ckan/i18n are an exception. These files are only ever changed on release branches following the Doing the beta release instructions above, and after a release has been finalized the changes need to be cherry-picked onto master.

To find out what i18n commits there are on the release-v* branch that are not on master, do:

```
git log master..dev-v* ckan/i18n
```

Then checkout the master branch, do a git status and a git pull to make sure you have the latest commits on master and no local changes. Then use git cherry-pick when on the master branch to cherry-pick these commits onto master. You should not get any merge conflicts. Run the check-po-files command again just to be safe, it should not report any problems. Run CKAN’s tests, again just to be safe. Then do git push origin master.

### 7.20.5 Preparing patch releases

1. Announce the release date & time with a week’s notice on ckan-announce.

   Often this will be part of the announcement of a CKAN major/minor release. But if patches go out separately then they will need their own announcement.

2. Update ckan/__init__.py with the incremented patch number e.g. 2.5.1 becomes 2.5.2. Commit the change and push the new branch to GitHub:

```
git commit -am "Update version number"
git push origin release-v2.5.2
```

3. Cherry-pick PRs marked for back-port.

   These are usually marked on Github using the Backport Pending labels and the relevant labels for the versions they should be cherry-picked to (eg Backport 2.5.3). Remember to look for PRs that are closed i.e. merged. Remove the Backport Pending label once the cherry-picking has been done (but leave the version ones).

4. Ask the tech team if there are security fixes or other fixes to include.

5. Update the CHANGELOG.

### 7.20.6 Doing the patch releases

1. If there have been any CSS or JS changes, rebuild the front-end.

   Rebuild the front-end, add new files and commit with:

```
paster front-end-build
git add ckan ckanext
git commit -am "Rebuild front-end"
```

2. Review the CHANGELOG to check it is complete.

3. Tag the repository with the version number.

   Make sure to push it to GitHub afterwards.
4. Create and deploy the final deb package.
   Create using ckan-packaging checkout e.g.:
   
   ```bash
   ./ckan-package -v 2.5.2 -i 1
   ```
   
   Make sure to rename the deb files so it follows the deb packages name convention:
   
   `python-ckan_Major.minor_amd64.deb`
   
   Note that we drop the patch version and iteration number from the package name.
   
   Move it to the root of the publicly accessible folder of the packaging server from the /build folder, replacing the existing file for this minor version.

5. Upload the release to PyPI:
   
   ```bash
   python setup.py sdist upload
   ```

6. Make sure the documentation branch (X.Y) is up to date with the latest changes in the corresponding dev-vX.Y branch.

7. Write a CKAN blog post and announce it to ckan-announce & ckan-dev & twitter.
   Often this will be part of the announcement of a CKAN major/minor release. But if patches go out separately then they will need their own announcement.
8.1 v.2.8.5 2020-08-05

Fixes:

- Add RTL support (#5413)
- Fix UnicodeDecodeError on abort function (#4829)
- Improve and reorder resource_formats.json (#5034)
- Allow passing arguments to the RQ enqueue_call function (#5208)
- Fix dashboard follower filter (#5412)
- Update dictionary.html for bs2 version (#5365)
- Prevent password reset exposing account presence (#5431)
- Add class dropdown to ‘New view’ menu (#5470)
- Update jQuery to 3.5.0 (#5364)
- Fix dashboard activity filter (#5424)
- Prevent account presence exposure when ckan.auth.public_user_details = false (#5432)
- Fix resource upload filename fetching in IE (#5438)
- Unflatten: allow nesting >1 level (#5444)
- Allow lists in resource extras (#5453)
- Only add error to tag_errors if not empty (#5454)
- Fix order_by param in user_list action (#5342)
- Fix for Resources validation errors display (#5335)
8.2 v.2.8.4 2020-04-15

General notes:

• Note: This version does not require a requirements upgrade on source installations
• Note: This version does not require a database upgrade
• Note: This version does not require a Solr schema upgrade
• Note: This version includes changes in the way the `SameSite` flag is set on the `auth_tkt` authorization cookie. The new default setting for it is `SameSite=Lax`, which aligns with the behaviour of all major browsers. If for some reason you need a different value, you can set it via the `who.samesite` configuration option. You can find more information on the `SameSite` attribute here.

Fixes:

• Fix for number of datasets displayed on the My organizations tab (#3580)
• Allow chaining of core actions (#4509)
• Password reset request - generally tighten it up (#4636)
• Fix start option in data_dict (#4920)
• Add missing get_action calls in activity actions (#4967)
• Fix datetime comparison in resource_dict_save (#5033)
• Fix wrong `_` function reference in user blueprint (#5046)
• Allow vocabulary_id in /api/2/util/tag/autocomplete (#5071)
• Fetch less data for `get_all_entity_ids` (#5201)
• Show error in text view if xhr failed (#5271)
• Fix code injection in autocomplete module (#5064)
• Check for the existence of tracking summary data before attempting to load it (#5030)
• Disable streaming for pylons requests (#4431)
• Filter revisions shown according to dataset permissions
• Fix wrong resource URL after ValidationErrors (#5152)
• Update JS vendor libraries
• SameSite support in auth cookie (#5255)
• Handle missing resources in case we have a race condition with the DataPusher (#3980)
• Add the `g` object to toolkit
• Use returned facets in group controller (#2713)
• Updated translations
• Fix broken translation in image view placeholder (#5099)

8.3 v.2.8.3 2019-07-03

General notes:

• Note: This version does not require a requirements upgrade on source installations
• Note: This version does not require a database upgrade
• Note: This version does not require a Solr schema upgrade

Fixes:
• Fix include_total in datastore_search (#4446)
• Fix problem with reindex-fast (#4352)
• Fix ValueError in url_validator (#4629)
• Strip local path when uploading file in IE (#4608)
• Increase size of h1 headings to 1.8em (#4665)
• Fix broken div nesting in the user/read_base.html (#4672)
• package_search parameter fl accepts list-like values (#4464)
• Use chained_auth_function with core auth functions (#4491)
• Allow translation of custom licenses (#4594)
• Fix delete button links (#4598)
• Fix hardcoded root paths (#4662)
• Fix reCaptcha (#4732)
• Fix incremented follower-counter (#4767)
• Fix breadcrumb on /datasets (#4405)
• Fix root_path when using mod_wsgi (#4452)
• Correctly insert root_path for urls generated with _external flag (#4722)
• Make reorder resources button translatable (#4838)
• Fix feeds urls generation (#4854)
• More robust auth functions for resource_view_show (#4827)
• Allow to customize the DataProxy URL (#4874)
• Allow custom CKAN callback URL for the DataPusher (#4878)
• Add psycopg>=2.8 support (#4841)

8.4 v.2.8.2 2018-12-12

General notes:
• This version requires a requirements upgrade on source installations
• Note: This version does not require a database upgrade
• Note: This version does not require a Solr schema upgrade

Fixes:
• Strip full URL on uploaded resources before saving to DB (#4382)
• Fix user not being defined in check_access function (#4574)
• Remove html5 shim from stats extension (#4236)
• Fix for datastore_search distinct=true option (#4236)
• Fix edit slug button (#4379)
• Don’t re-register plugin helpers on flask_app (#4414)
• Fix for Resource View Re-order (#4416)
• autocomplete.js: fix handling of comma key codes (#4421)
• Flask patch update (#4426)
• Allow plugins to define multiple blueprints (#4495)
• Fix i18n API encoding (#4505)
• Allow to defined legacy route mappings as a dict in config (#4521)
• group_patch does not reset packages (#4557)

8.5 v.2.8.1 2018-07-25

General notes:
• Note: This version does not requires a requirements upgrade on source installations
• Note: This version does not requires a database upgrade
• Note: This version does not require a Solr schema upgrade

Fixes:
• “Add Filter” Performance Issue (#4162)
• Error handler update (#4257)
• “New view” button does not work (#4260)
• Upload logo is not working (#4262)
• Unable to pip install ckan (#4271)
• The “License” Icon in 2.8 is wrong (#4272)
• Search - input- border color is overly specific in CSS (#4273)
• Site logo image does not scale down when very large (#4283)
• Validation Error on datastore_search when sorting timestamp fields (#4288)
• Undocumented changes breaking error_document_template (#4303)
• Internal server error when viewing /dashboard when logged out (#4305)
• Missing c.action attribute in 2.8.0 templates (#4310)
• [multilingual] AttributeError: ‘_Globals’ object has no attribute ‘fields’ (#4338)
• search legacy route missing (#4346)
8.6 v.2.8.0 2018-05-09

General notes:

- This version requires a requirements upgrade on source installations
- This version requires a database upgrade
- This version requires a Solr schema upgrade
- This version requires re-running the `datastore set-permissions` command (assuming you are using the DataStore). See: [Set permissions](#)

Otherwise new and updated datasets will not be searchable in DataStore and the logs will contain this error:

```
ProgrammingError: (psycopg2.ProgrammingError) function populate_full_text_.
    trigger() does not exist
```

CKAN developers should also re-run set-permissions on the test database: [Set up the test databases](#)

- There are several old features being officially deprecated starting from this version. Check the [Deprecations](#) section to be prepared.

Major changes:

- New revamped frontend templates based on Bootstrap 3, see “Changes and deprecations” (#3547)
- Allow datastore_search_sql on private datasets (#2562)
- New Flask blueprints migrated from old Pylons controllers: user, dashboard, feeds, admin and home (#3927, #3870, #3775, #3762)
- Improved support for custom groups and organization types (#4032)
- Hide user details to anonymous users (#3915)

Minor changes:

- Allow chaining of authentication functions (#3679)
- Show custom dataset types in search pages (#3807)
- Overriding datastore authorization system (#3679)
- Standardize on url_for (#3831)
- Deprecate notify_after_commit (#3633)
- _mail_recipient header override (#3781)
- Restrict access to member forms (#3684)
- Clean up template rendering code (#3923)
- Permission labels are indexed by type text in SOLR (#3863)
- CLI commands require a Flask test request context (#3760)
- Allow IValidator to override existing validators (#3865)
- Shrink datastore_create response size (#3810)
- Stable version URLs CKAN for documentation (#4209)
- API Documentation update (#4136)
- Documentation of Data Dictionary (#3989)

8.6. v.2.8.0 2018-05-09
• Remove datastore legacy mode (#4041)
• Map old Pylons routes to Flask ones (#4066)

Bug fixes:
• File uploads don’t work on new Flask based API (#3869)
• `{ % ckan_extends % }` not working on templates served by Flask (#4044)
• Problems in background workers with non-core database relations (#3606)
• `Render_datetime` can’t handle dates before year 1900 (#2228)
• DatapusherPlugin implementation of notify() can call ‘datapusher_submit’ multiple times (#2334)
• Dataset creation page generates incorrect URLs with Chrome autocomplete (#2501)
• Search buttons need accessible labels (#2550)
• Column name length limit for datastore upload (#2804)
• #2373: Do not validate packages or resources from database to views (#3016)
• Creation of dataset - different behaviour between Web API & CKAN Interface functionality (#3528)
• Redirecting to same page in non-root hosted ckan adds extra root_path to url (#3499)
• Beaker 1.8.0 exception when the code is served from OSX via Vagrant (#3512)
• Add “Add Dataset” button to user’s and group’s page (#2794)
• Some links in CKAN is not reachable (#2898)
• Exception when specifying a directory in the ckan.i18n_directory option (#3539)
• Resource view filter user filters JS error (#3590)
• Recaptcha v1 will stop working 2018-3-31 (#4061)
• “Testing coding standards” page in docs is missing code snippets (#3635)
• Followers count not updated immediately on UI (#3639)
• Increase jQuery version (#3665)
• Search icon on many pages is not properly vertically aligned (#3654)
• Datatables view can’t be used as a default view (#3669)
• Resource URL is not validated on create/update (#3660)
• Upload to Datastore tab shows incorrect time at Upload Log (#3588)
• Filter results button is not working (#3593)
• Broken link in “Upgrading CKAN’s dependencies” doc page (#3637)
• Default logo image not properly saved (#3656)
• Activity test relies on datetime.now() (#3644)
• Info block text for Format field not properly aligned in resource form page (#3663)
• Issue upon creating new organization/group through UI form (#3661)
• In API docs “package_create” lists “owner_org” as optional (#3647)
• Embed modal window not working (#3731)
• Frontend build command does not work on master (#3688)
• Loading image duplicated (#3716)
• Datastore set-up error - logging getting in the way (#3694)
• Registering a new account redirects to an unprefixed url (#3834)
• Exception in search page when not authorized (#4081)
• Datastore full-text-search column is populated by postgres trigger rather than python (#3785)
• Datastore dump results are not the same as data in database (#4150)
• Adding filter at resource preview doesn’t work while site is setup with ckan.root_path param (#4140)
• No such file or directory: ‘/usr/lib/ckan/default/src/ckan/requirement-setuptools.txt’ during installation from source (#3641)
• Register user form missing required field indicators (#3658)
• Datastore full-text-search column is populated by postgres trigger rather than python (#3786)
• Add missing major changes to change log (#3799)
• Paster/CLI config-tool requires _get_test_app which in turn requires a dev-only dependency (#3806)
• Change log doesn’t mention necessary Solr scheme upgrade (#3851)
• TypeError: expected byte string object, value of type unicode found (#3921)
• CKAN’s state table clashes with PostGIS generated TIGER state table (#3929)
• [Docker] entrypoint initdb.d sql files copied to root (#3939)
• DataStore status page throws TypeError - Bleach upgrade regression (#3968)
• Source install error with who.ini (#4020)
• making a JSONP call to the CKAN API returns the wrong mime type (#4022)
• Deleting a resource sets datastore_active=False to all resources and overrides their extras (#4042)
• Deleting first Group and Organization custom field is not possible (#4094)

Changes and deprecations:

• The default templates included in CKAN core have been updated to use Bootstrap 3. Extensions implementing custom themes are encouraged to update their templates, but they can still make CKAN load the old Bootstrap 2 templates during the transition using the following configuration options:

```
ckan.base_public_folder = public-bs2
ckan.base_templates_folder = templates-bs2
```

• The API versions 1 and 2 (also known as the REST API), ie /api/rest/* have been completely removed in favour of the version 3 (action API, /api/action/*).

• The old Celery based background jobs have been removed in CKAN 2.8 in favour of the new RQ based jobs (http://docs.ckan.org/en/latest/maintaining/background-tasks.html). Extensions can still of course use Celery but they will need to handle the management themselves.

• The ckan.recaptcha.version config option is now removed, since v2 is the only valid version now (#4061)
8.7 v2.7.5 2018-12-12

- Strip full URL on uploaded resources before saving to DB (#4382)
- Fix for datastore_search distinct=true option (#4236)
- Fix edit slug button (#4379)
- Don’t re-register plugin helpers on flask_app (#4414)
- Fix for Resource View Re-order (#4416)
- autocomplete.js: fix handling of comma key codes (#4421)
- Flask patch update (#4426)
- Allow plugins to define multiple blueprints (#4495)
- Fix i18n API encoding (#4505)
- Allow to defined legacy route mappings as a dict in config (#4521)
- group_patch does not reset packages (#4557)

8.8 v2.7.4 2018-05-09

- Adding filter at resource preview doesn’t work while site is setup with ckan.root_path param (#4140)
- Datastore dump results are not the same as data in database (#4150)

8.9 v2.7.3 2018-03-15

General notes:

- As with all patch releases this one does not include requirement changes. However in some scenarios you might encounter the following error while installing or upgrading this version of CKAN:

```
Error: could not determine PostgreSQL version from '10.2'
```

This is due to a bug in the psycopg2 version pinned to the release. To solve it, upgrade psycopg2 with the following command:

```
pip install --upgrade psycopg2==2.7.3.2
```

- This release does not require a Solr schema upgrade, but if you are having the issues described in #3863 (datasets wrongly indexed in multilingual setups), you can upgrade the Solr schema and reindex to solve them.
- #3422 (implemented in #3425) introduced a major bug where if a resource was deleted and the DataStore was active extras from all resources on the site where changed. This is now fixed as part of this release but if your database is already affected you will need to run a script to restore the extras to their previous state. Remember, you only need to run the script if all the following are true:
  1. You are currently running CKAN 2.7.0 or 2.7.2, and
  2. You have enabled the DataStore, and
  3. One or more resources with data on the DataStore have been deleted (or you suspect they might have been)
If all these are true you can run the following script to restore the extras to their previous state:

https://github.com/ckan/ckan/blob/dev-v2.7/scripts/4042_fix_resource_extras.py

This issue is described in #4042

Fixes:

• Fix toggle bars header icon (#3880)
• Change CORS header keys and values to string instead of unicode (#3855)
• Fix cors header when all origins are allowed (#3898)
• Update SOLR schema.xml reference in Dockerfile
• Build local SOLR container by default
• Create datastore indexes only if they are not exist
• Properly close file responses
• Use javascript content-type for jsonp responses (#4022)
• Add Data Dictionary documentation (#3989)
• Fix SOLR index delete_package implementation
• Add second half of DataStore set-permissions command(Docs)
• Fix extras overriding for removed resources (#4042)
• Return a 403 if not authorized on the search page (#4081)
• Add support for user/pass for Solr as ENV var
• Change permission_labels type to string in schema.xml (#3863)
• Disallow solr local parameters
• Improve text view rendering
• Update Orgs/Groups logic for custom fields delete and update (#4094)
• Upgrade Solr Docker image

8.10 v2.7.2 2017-09-28

• Include missing minified JavaScript files

8.11 v2.7.1 2017-09-27

• add field_name to image_upload macro when uploading resources (#3766)
• Add some missing major changes to change log. (#3799)
• _mail_recipient header override (#3781)
• skip url parsing in redirect (#3499)
• Fix multiple errors in i18n of JS modules (#3590)
• Standardize on url_for on popup (#3831)
CKAN documentation, Release 2.8.5

8.12 v2.7.0 2017-08-02

General notes:

• Starting from this version, CKAN requires at least Postgres 9.3
• Starting from this version, CKAN requires a Redis database. Please refer to the new ckan.redis.url configuration option.
• This version requires a requirements upgrade on source installations
• This version requires a database upgrade
• This version requires a Solr schema upgrade
• There are several old features being officially deprecated starting from this version. Check the Deprecations section to be prepared.

Major changes:

• New datatables_view resource view plugin for tabular data (#3444)
• IDataStoreBackend plugins for replacing the default DataStore Postgres backend (#3437)
• datastore_search new result formats and performance improvements (#3523)
• PL/PGSQL triggers for DataStore tables (#3428)
• DataStore dump CLI commands (#3384)
• Wrap/override actions defined in other plugins (#3494)
• DataStore table data dictionary stored as postgres comments (#3414)
• Common session object for Flask and Pylons (#3208)
• Rename deleted datasets when they conflict with new ones (#3370)
• DataStore dump more formats: CSV, TSV, XML, JSON; BOM option (#3390)
• Common requests code for Flask and Pylons (#3312)
• Generate complete datastore dump files (#3344)
• A new system for asynchronous background jobs (#3165)

Minor changes:

• Renamed example theme plugin (#3576)
• Localization support for groups (#3559)
• Create new resource views when format changes (#3515)
• Email field validation (#3568)
• datastore_run_triggers sysadmin-only action to apply triggers to existing data (#3565)
• Docs updated for Ubuntu 16.04 (#3544)
• Upgrade leaflet to 0.7.7 (#3534)
• Datapusher CLI always-answer-yes option (#3524)
• Added docs for all plugin interfaces (#3519)
• DataStore dumps nested columns as JSON (#3487)
• Faster/optional datastore_search total calculation (#3467)
- Faster group_activity_query (#3466)
- Faster query performance (#3430)
- Marked remaining JS strings translatable (#3423)
- Upgrade font-awesome to 4.0.3 (#3400)
- group/organization_show include_dataset_count option (#3385)
- image_formats config option for image viewer (#3380)
- click may now be used for CLI interfaces: use load_config instead of CkanCommand (#3384)
- package_search option to return only names/ids (#3427)
- user_list all_fields option (#3353)
- Error controller may now be overridden (#3340)
- Plural translations in JS (#3211)
- Support JS translations in extensions (#3272)
- Requirements upgraded (#3305)
- Dockerfile updates (#3295)
- Fix activity test to use utcnow (#3644)
- Changed required permission from ‘update’ to ‘manage_group’ (#3631)
- Catch invalid sort param exception (#3630)
- Choose direction of recreated package relationship depending on its type (#3626)
- Fix render_datetime for dates before year 1900 (#3611)
- Fix KeyError in ‘package_create’ (#3027)
- Allow slug preview to work with autocomplete fields (#2501)
- Fix filter results button not working for organization/group (#3620)
- Allow underscores in URL slug preview on create dataset (#3612)
- Fallback to po file translations on h.get_translated() (#3577)
- Fix Fanstatic URL on non-root installs (#3618)
- Fixed escaping issues with helpers.mail_to and datapusher logs
- Autocomplete fields are more responsive - 300ms timeout instead of 1s (#3693)
- Fixed dataset count display for groups (#3711)
- Restrict access to form pages (#3684)
- Render_datetime can handle dates before year 1900 (#2228)

**API changes:**

- `organization_list_for_user` (and the `h.organizations_available()` helper) now return all organizations a user belongs to regardless of capacity (Admin, Editor or Member), not just the ones where she is an administrator (#2457)

- `organization_list_for_user` (and the `h.organizations_available()` helper) now default to not include package_count. Pass include_dataset_count=True if you need the package_count values.
• `resource['size']` will change from string to long integer (#3205)

• Font Awesome has been upgraded from version 3.2.1 to 4.0.3. Please refer to https://github.com/FortAwesome/Font-Awesome/wiki/Upgrading-from-3.2.1-to-4 to upgrade your code accordingly if you are using custom themes.

Deprecations:

• The API versions 1 and 2 (also known as the REST API, ie /api/rest/* will removed in favour of the version 3 (action API, /api/action/*), which was introduced in CKAN 2.0. The REST API will be removed on CKAN 2.8.

• The default theme included in CKAN core will switch to use Bootstrap 3 instead of Bootstrap 2 in CKAN 2.8. The current Bootstrap 2 based templates will still be included in the next CKAN versions, so existing themes will still work. Bootstrap 2 templates will be eventually removed though, so instances are encouraged to update their themes using the available documentation (https://getbootstrap.com/migration/)

• The activity stream related actions ending with _list (eg package_activity_list) and _html (eg package_activity_list_html) will be removed in CKAN 2.8 in favour of more efficient alternatives and are now deprecated.

• The legacy revisions controller (ie /revisions/*) will be completely removed in CKAN 2.8.

• The old Celery based background jobs will be removed in CKAN 2.8 in favour of the new RQ based jobs (http://docs.ckan.org/en/latest/maintaining/background-tasks.html). Extensions can still of course use Celery but they will need to handle the management themselves.

8.13 v2.6.7 2018-12-12

• Fix for Resource View Re-order (#4416)

• autocomplete.js: fix handling of comma key codes (#4421)

• group_patch does not reset packages (#4557)

8.14 v2.6.6 2018-05-09

• Adding filter at resource preview doesn’t work while site is setup with ckan.root_path param (#4140)

• Stable version URLs CKAN for documentation (#4209)

• Add Warning in docs sidebar (#4209)

8.15 v2.6.5 2018-03-15

Note: This version requires a database upgrade

• Activity Time stored in UTC (#2882)

• Migration script to adjust current activity timestamps to UTC

• Change CORS header keys and values to string instead of unicode (#3855)

• Fix cors header when all origins are allowed (#3898)

• Update SOLR schema.xml reference in Dockerfile
• Build local SOLR container by default
• Create datastore indexes only if they don’t exist
• Properly close file responses
• Use javascript content-type for jsonp responses (#4022)
• Fix SOLR index delete_package implementation
• Add second half of DataStore set-permissions command (Docs)
• Return a 403 if not authorized on the search page (#4081)
• Add support for user/pass for Solr as ENV var
• Disallow solr local parameters
• Improve text view rendering
• Update Orgs/Groups logic for custom fields delete and update (#4094)

8.16 v2.6.4 2017-09-27

• Mail recepient header override (#3781)
• Skip url parsing in redirect (#3499)
• Support non root for fanstatic (#3618)

8.17 v2.6.3 2017-08-02

• Fix in organization / group form image URL field (#3661)
• Fix activity test to use utcnow (#3644)
• Changed required permission from ‘update’ to ‘manage_group’ (#3631)
• Catch invalid sort param exception (#3630)
• Choose direction of recreated package relationship depending on its type (#3626)
• Fix render_datetime for dates before year 1900 (#3611)
• Fix KeyError in ‘package_create’ (#3027)
• Allow slug preview to work with autocomplete fields (#2501)
• Fix filter results button not working for organization/group (#3620)
• Allow underscores in URL slug preview on create dataset (#3612)
• Create new resource view if resource format changed (#3515)
• Fixed escaping issues with helpers.mail_to and datapusher logs
• Autocomplete fields are more responsive - 300ms timeout instead of 1s (#3693)
• Fixed dataset count display for groups (#3711)
• Restrict access to form pages (#3684)
8.18 v2.6.2 2017-03-22

- Use fully qualified urls for reset emails (#3486)
- Fix edit_resource for resource with draft state (#3480)
- Tag fix for group/organization pages (#3460)
- Setting of datastore_active flag moved to separate function (#3481)

8.19 v2.6.1 2017-02-22

- Fix DataPusher being fired multiple times (#3245)
- Use the url_for() helper for datapusher URLs (#2866)
- Resource creation date use datetime.utcnwo() (#3447)
- Fix locale error when using fix ckan.root_path
- render_markdown breaks links with ampersands
- Check group name and id during package creation
- Use utcnwo() on dashboard_mark_activities_old (#3373)
- Fix encoding error on DataStore exception
- Datastore doesn’t add site_url to resource created via API (#3189)
- Fix memberships after user deletion (#3265)
- Remove idle database connection (#3260)
- Fix package_owner_org_update action when called via the API (#2661)
- Fix French locale (#3327)
- Updated translations

8.20 v2.6.0 2016-11-02

Note: Starting from this version, CKAN requires at least Python 2.7 and Postgres 9.2
Note: This version requires a requirements upgrade on source installations
Note: This version requires a database upgrade

Note: This version does not require a Solr schema upgrade (You may want to upgrade the schema if you want to target Solr>=5, see #2914)

Major:

- Private datasets are now included in the default dataset search results (#3191)
- package_search API action now has an include_private parameter (#3191)

Minor:

- Make resource name default to file name (#1372)
- Customizable email templates (#1527)
• Change solrpy library to pysolr (#2352)
• Cache SQL query results (#2353)
• File Upload UX improvements (#2604)
• Helpers for multilingual fields (#2678)
• Improve Extension translation docs (#2783)
• Decouple configuration from Pylons (#3163)
• toolkit: add h, StopOnError, DefaultOrganizationForm (#2835)
• Remove Genshi support (#2833)
• Make resource URLs optional (#2844)
• Use 403 when actions are forbidden, not 401 (#2846)
• Upgrade requirements version (#3004, #3005)
• Add icons sources (#3048)
• Remove lib/dumper (#2879)
• ckan.__version__ available as template helper (#3103)
• Remove site_url_nice from app_globals (#3117)
• Remove e.message deprecation warning when running tests (#3121)
• Drop Python 2.6 support (#3126)
• Update Recline version (#3184)
• Refactor config/middleware.py to more closely match poc-flask-views (#3116)
• Creation of datasets sources with no organization specified (#3046)

Bug fixes:
• DataPusher called multiple times when creating a dataset (#2856)
• Default view is re-added when removed before DataStore upload is complete (#3011)
• “Data API” button disappears on resource page after empty update (#3012)
• Uncaught email exceptions on user invite (#3077)
• Resource view description is not rendered as Markdown (#3128)
• Fix broken html5lib dependency (#3180)
• ZH_cn translation formatter fix (#3238)
• Incorrect i18n-paths in extension’s setup.cfg (#3275)
• Changing your user name produces an error and logs you out (#2394)
• Fix “Load more” functionality in the dashboard (#2346)
• Fix filters not working when embedding a resource view (#2657)
• Proper sanitation of header name on SlickGrid view (#2923)
• Fix unicode error when indexing field of type JSON (#2969)
• Fix group feeds returning no datasets (#2955)
• Replace MapQuest tiles in Recline with Stamen Terrain (#3162)
• Fix bulk operations not taking effect (#3199)
• Raise validation errors on group/org_member_create (#3108)
• Incorrect warnings when ckan.views.default_views is empty (#3093)
• Don’t show deleted users/datasets on member_list (#3078)
• Fix Tag pagination widget styling (#2399)
• Fix package_owner_org_update standalone (#2661)
• Don’t template fanstatic error pages (#2770)
• group_controller() on IGroupForm not in interface (#2771)
• Fix assert_true to test for message in response (#2802)
• Add user parameter to paster profile command (#2815)
• make context['user'] always username or None (#2817)
• remove some deprecated compatibility hacks (#2818)
• Param use_default_schema does not work on package_search (#2848)
• Sanitize offset when listing group activity (#2859)
• Incorrect ‘download resource’ hyperlink when a resource is unable to upload to datastore (#2873)
• Resolve datastore_delete erasing the database when filters was blank. (#2885)
• DomainObject.count() doesn’t return count (#2919)
• Fix response code test failures (#2931)
• Fixed the url_for_* helpers when both SCRIPT_NAME and ckan.root_path are defined (#2936)
• Escape special characters in password while db loading (#2952)
• Fix redirect not working with non-root (#2968)
• Group pagination does not preserve sort order (#2981)
• Remove LazyJSONObject (#2983)
• Deleted users appear in sysadmin user lists (#2988)
• Server error at /organization if not authorized to list organizations (#2990)
• Slow page rendering when using lots of snippets (#3000)
• Only allow JSONP callbacks on GET requests (#3002)
• Attempting to access non-existing helpers should raise HelperException (#3041)
• Deprecate h.url, make it use h.url_for internally (#3055)
• Tests fail when LANG environment variable is set to German (#3060)
• Fix pagination style (CSS) (#3067)
• Login fails with 404 when using root_path (#3089)
• Resource view description is not rendered as Markdown (#3128)
• Clarify package_relationship_update documentation (#3132)
• q parameter in followee_list action has no effect (#3167)
• Zh cn translation formatter fix (#3238)
• Users are not removed in related tables if the main user entry is deleted (#3265)

**API changes and deprecations:**

• Replace `c.__version__` with new helper `h.ckan_version()` (#3103)

### 8.21 v2.5.8 2018-03-15

Note: This version requires a database upgrade

- Fix language switcher
- Activity Time stored in UTC (#2882)
- Migration script to adjust current activity timestamps to UTC
- Change CORS header keys and values to string instead of unicode (#3855)
- Fix cors header keys when all origins are allowed (#3898)
- Create datastore indexes only if they are not exist
- Use javascript content-type for jsonp responses (#4022)
- Fix SOLR index delete_package implementation
- Add second half of DataStore set-permissions command(Docs)
- Update SOLR client (pysolr -> solrpy)
- Return a 403 if not authorized on the search page (#4081)
- Add support for user/pass for Solr as ENV var
- Disallow solr local parameters
- Improve text view rendering
- Update Orgs/Groups logic for custom fields delete and update (#4094)

### 8.22 v2.5.7 2017-09-27

- Allow overriding email headers (#3781)
- Support non-root instances on fanstatic (#3618)
- Add missing close button on organization page (#3814)

### 8.23 v2.5.6 2017-08-02

- Fix in organization / group form image URL field (#3661)
- Fix activity test to use utcnow (#3644)
- Changed required permission from ‘update’ to ‘manage_group’ (#3631)
- Catch invalid sort param exception (#3630)
- Choose direction of recreated package relationship depending on its type (#3626)
- Fix render_datetime for dates before year 1900 (#3611)
• Fix KeyError in ‘package_create’ (#3027)
• Allow slug preview to work with autocomplete fields (#2501)
• Fix filter results button not working for organization/group (#3620)
• Allow underscores in URL slug preview on create dataset (#3612)
• Create new resource view if resource format changed (#3515)
• Fixed incorrect escaping in mail_to and datapusher’s log
• Autocomplete fields are more responsive - 300ms timeout instead of 1s (#3693)
• Fixed dataset count display for groups (#3711)
• Restrict access to form pages (#3684)

8.24 v2.5.5 2017-03-22

• Use fully qualified urls for reset emails (#3486)
• Fix edit_resource for resource with draft state (#3480)
• Tag fix for group/organization pages (#3460)
• Setting of datastore_active flag moved to separate function (#3481)

8.25 v2.5.4 2017-02-22

• Fix DataPusher being fired multiple times (#3245)
• Use the url_for() helper for datapusher URLs (#2866)
• Resource creation date use datetime.utcnow() (#3447)
• Fix locale error when using ckan.root_path
• render_markdown breaks links with ampersands
• Check group name and id during package creation
• Use utcnow() on dashboard_mark_activities_old (#3373)
• Fix encoding error on DataStore exception
• Datastore doesn’t add site_url to resource created via API (#3189)
• Fix memberships after user deletion (#3265)
• Remove idle database connection (#3260)
• Fix package_owner_org_update action when called via the API (#2661)

8.26 v2.5.3 2016-11-02

• DataPusher called multiple times when creating a dataset (#2856)
• Default view is re-added when removed before DataStore upload is complete (#3011)
• “Data API” button disappears on resource page after empty update (#3012)
• Uncaught email exceptions on user invite (#3077)
• Resource view description is not rendered as Markdown (#3128)
• Fix broken html5lib dependency (#3180)
• ZH_cn translation formatter fix (#3238)
• Incorrect i18n-paths in extension’s setup.cfg (#3275)
• Changing your user name produces an error and logs you out (#2394)
• Fix “Load more” functionality in the dashboard (#2346)
• Fix filters not working when embedding a resource view (#2657)
• Proper sanitation of header name on SlickGrid view (#2923)
• Fix unicode error when indexing field of type JSON (#2969)
• Fix group feeds returning no datasets (#2955)
• Replace MapQuest tiles in Recline with Stamen Terrain (#3162)
• Fix bulk operations not taking effect (#3199)
• Raise validation errors on group/org_member_create (#3108)
• Incorrect warnings when ckan.views.default_views is empty (#3093)
• Don’t show deleted users/datasets on member_list (#3078)

8.27 v2.5.2 2016-03-31

Bug fixes:

• Avoid submitting resources to the DataPusher multiple times (#2856)
• Use resource.url as raw_resource_url (#2873)
• Fix DomainObject.count() to return count (#2919)
• Prevent unicode/ascii conversion errors in DataStore
• Fix datastore_delete erasing the db when filters is blank (#2885)
• Avoid package_search exception when using use_default_schema (#2848)
• Encode EXPLAIN SQL before sending to datastore
• Use ckan.site_url to generate urls of resources (#2592)
• Fixed the url for the organization_item template

8.28 v2.5.1 2015-12-17

Note: This version requires a requirements upgrade on source installations
Note: This version requires a database upgrade
Note: This version does not require a Solr schema upgrade

Major:

• CKAN extension language translations integrated using ITranslations interface (#2461, #2643)
• Speed improvements for displaying a dataset (#2234), home page (#2554), searching (#2382, #2724) and API actions: package_show (#1078) and user_list (#2752).

• An interface to replace the file uploader, allowing integration with other cloud storage providers (IUploader interface) (#2510)

Minor:

• package_purge API action added (#1572)
• revision_list API action now has paging (#1431)
• Official Ubuntu 14.04 LTS support (#1651)
• Require(validate) current password before allowing a password change (#1940)
• recline_map_view now recognizes GeoJSON fileds (#2387)
• Timezone setting (#2494)
• Updating a resource via upload now saves the last_modified value in the resource (#2519)
• DataPusher can be customized using the new IDataPusher interface (#2571)
• Exporting and importing users, with their passwords (if sysadmin) (#2647)

Bug fixes:

• Fix to allow uppercase letters in local part of email when sending user invitations (#2415)
• License pick-list changes would cause old values in datasets to be overwritten when edited (#2472)
• Schema was being passed to package_create_default_resource_views (#2484)
• Arabic translation format string issue (#2493)
• Error when deleting organizations (#2512)
• When DataPusher had an error storing a resource in Data Store, the resource data page gave an error (#2518)
• Data preview failed when it comes from a server that gives 403 error from a HEAD request (#2530)
• ‘paster views create’ failed for non-default dataset types (#2532)
• DataPusher didn’t work for TSV files (#2553)
• DataPusher failed sometimes due to ‘type mismatch’ (#2581)
• IGroupForm wasn’t allowing new groups (of type ‘group’) to use group_form (#2617, #2640)
• group_purge left behind a Member if it has a parent group/org (#2631)
• organization_purge left orphaned datasets still with owner_id (#2632)
• Fix Markdown rendering issue
• Return default error page on fanstatic errors
• Prevent authentication when using API callbacks

8.28.1 Changes and deprecations

• The old RDF templates to output a dataset in RDF/XML or N3 format have been removed. These can be now enabled using the dcat plugin on ckanext-dcat:
  https://github.com/ckan/ckanext-dcat#rdf-dcat-endpoints
• The library used to render markdown has been changed to python-markdown. This introduces both python-markdown and bleach as dependencies, as bleach is used to clean any HTML provided to the markdown processor.

• This is the last version of CKAN to support Postgresql 8.x, 9.0 and 9.1. The next minor version of CKAN will require Postgresql 9.2 or later.

8.29 v2.5.0 2015-12-17

Cancelled release

8.30 v2.4.9 2017-09-27

• Allow overriding email headers (#3781)
• Support non-root instances on fanstatic (#3618)
• Add missing close button on organization page (#3814)

8.31 v2.4.8 2017-08-02

• Fix in organization / group form image URL field (#3661)
• Fix activity test to use utcnw (#3644)
• Changed required permission from 'update' to 'manage_group' (#3631)
• Catch invalid sort param exception (#3630)
• Choose direction of recreated package relationship depending on its type (#3626)
• Fix render_datetime for dates before year 1900 (#3611)
• Fix KeyError in 'package_create' (#3027)
• Allow slug preview to work with autocomplete fields (#2501)
• Fix filter results button not working for organization/group (#3620)
• Allow underscores in URL slug preview on create dataset (#3612)
• Create new resource view if resource format changed (#3515)
• Fixed incorrect escaping in mail_to
• Autocomplete fields are more responsive - 300ms timeout instead of 1s (#3693)
• Fixed dataset count display for groups (#3711)
• Restrict access to form pages (#3684)

8.32 v2.4.7 2017-03-22

• Use fully qualified urls for reset emails (#3486)
• Fix edit_resource for resource with draft state (#3480)
• Tag fix for group/organization pages (#3460)
• Fix for package_search context (#3489)

8.33 v2.4.6 2017-02-22

• Use the url_for() helper for datapusher URLs (#2866)
• Resource creation date use datetime.utcnow() (#3447)
• Fix locale error when using fix ckan.root_path
• render_markdown breaks links with ampersands
• Check group name and id during package creation
• Use utcnow() on dashboard_mark_activities_old (#3373)
• Fix encoding error on DataStore exception
• Datastore doesn’t add site_url to resource created via API (#3189)
• Fix memberships after user deletion (#3265)
• Remove idle database connection (#3260)
• Fix package_owner_org_update action when called via the API (#2661)

8.34 v2.4.5 2017-02-22

Cancelled release

8.35 v2.4.4 2016-11-02

• Changing your user name produces an error and logs you out (#2394)
• Fix “Load more” functionality in the dashboard (#2346)
• Fix filters not working when embedding a resource view (#2657)
• Proper sanitation of header name on SlickGrid view (#2923)
• Fix unicode error when indexing field of type JSON (#2969)
• Fix group feeds returning no datasets (#2955)
• Replace MapQuest tiles in Recline with Stamen Terrain (#3162)
• Fix bulk operations not taking effect (#3199)
• Raise validation errors on group/org_member_create (#3108)
• Incorrect warnings when ckan.views.default_views is empty (#3093)
• Don’t show deleted users/datasets on member_list (#3078)
8.36 v2.4.3 2016-03-31

Bug fixes:

- Use resource.url as raw_resource_url (#2873)
- Fix DomainObject.count() to return count (#2919)
- Add offset param to organization_activity (#2640)
- Prevent unicode/ascii conversion errors in DataStore
- Fix datastore_delete erasing the db when filters is blank (#2885)
- Avoid package_search exception when using use_default_schema (#2848)
- resource_edit incorrectly setting action to new instead of edit
- Encode EXPLAIN SQL before sending to datastore
- Use ckan.site_url to generate urls of resources (#2592)
- Don’t hide actual exception on paster commands

8.37 v2.4.2 2015-12-17

Note: This version requires a requirements upgrade on source installations

Bug fixes:

- Fix Markdown rendering issue
- Return default error page on fanstatic errors
- Prevent authentication when using API callbacks

8.38 v2.4.1 2015-09-02

Note: #2554 fixes a regression where group_list and organization_list where returning extra additional fields by default, causing performance issues. This is now fixed, so the output for these actions no longer returns users, extras, etc. Also, on the homepage template the c.groups and c.group_package_stuff context variables are no longer available.

Bug fixes:

- Fix dataset count in templates and show datasets on featured org/group (#2557)
- Fix autodetect for TSV resources (#2553)
- Improve character escaping in DataStore parameters
- Fix “paster db init” when celery is configured with a non-database backend
- Fix severe performance issues with groups and orgs listings (#2554)
Note: This version requires a database upgrade
Note: This version requires a Solr schema upgrade

**Major:**
- CKAN config can now be set from environment variables and via the API (#2429)

**Minor:**
- API calls now faster: group_show, organization_show, user_show, package_show, vocabulary_show & tag_show (#1886, #2206, #2207, #2376)
- Require/validate current password before allowing a password change (#1940)
- Added organization_autocomplete action (#2125)
- Default authorization no longer allows anyone to create datasets etc (#2164)
- organization_list_for_user now returns organizations in hierarchy if they exist for roles set in ckan.auth.roles_that_cascade_to_sub_groups (#2199)
- Improved accessibility (text based browsers) focused on the page header (#2258)
- Improved IGroupForm for better customizing groups and organization behaviour (#2354)
- Admin page can now be extended to have new tabs (#2351)

**Bug fixes:**
- Command line paster user failed for non-ascii characters (#1244)
- Memory leak fixed in datastore API (#1847)
- Modifying resource didn’t update it’s last updated timestamp (#1874)
- Datastore didn’t update if you uploaded a new file of the same name as the existing file (#2147)
- Files with really long file were skipped by datapusher (#2057)
- Multi-lingual Solr schema is now updated so it works again (#2161)
- Resource views didn’t display when embedded in another site (#2238)
- resource_update failed if you supplied a revision_id (#2340)
- Recline could not plot GeoJSON on a map (#2387)
- Dataset create form 404 error if you added a resource but left it blank (#2392)
- Editing a resource view for a file that was UTF-8 and had a BOM gave an error (#2401)
- Email invites had the email address changed to lower-case (#2415)
- Default resource views not created when using a custom dataset schema (#2421, #2482)
- If the licenses pick-list was customized to remove some, datasets with old values had them overwritten when edited (#2472)
- Recline views failed on some non-ascii characters (#2490)
- Resource proxy failed if HEAD responds with 403 (#2530)
- Resource views for non-default dataset types couldn’t be created (#2532)
8.39.1 Changes and deprecations

- The default of allowing anyone to create datasets, groups and organizations has been changed to False. It is advised to ensure you set all of the Authorization Settings options explicitly in your CKAN config. (#2164)

- The package_show API call does not return the tracking_summary, keys in the dataset or resources by default any more.

  Any custom templates or users of this API call that use these values will need to pass: include_tracking=True.

- The legacy tests directory has moved to tests/legacy, the new_tests directory has moved to tests and the new_authz.py module has been renamed authz.py. Code that imports names from the old locations will continue to work in this release but will issue a deprecation warning. (#1753)

- group_show and organization_show API calls no longer return the datasets by default (#2206)

  Custom templates or users of this API call will need to pass include_datasets=True to include datasets in the response.

- The vocabulary_show and tag_show API calls no longer returns the packages key - i.e. datasets that use the vocabulary or tag. However tag_show now has an include_datasets option. (#1886)

- Config option site_url is now required - CKAN will not abort during start-up if it is not set. (#1976)

8.40 v2.3.5 2016-11-02

- Fix “Load more” functionality in the dashboard (#2346)

- Fix filters not working when embedding a resource view (#2657)

- Proper sanitation of header name on SlickGrid view (#2923)

- Fix unicode error when indexing field of type JSON (#2969)

- Fix group feeds returning no datasets (#2955)

- Replace MapQuest tiles in Recline with Stamen Terrain (#3162)

- Fix bulk operations not taking effect (#3199)

- Raise validation errors on group/org_member_create (#3108)

- Incorrect warnings when ckan.views.default_views is empty (#3093)

- Don’t show deleted users/datasets on member_list (#3078)

8.41 v2.3.4 2016-03-31

Bug fixes:

- Use resource.url as raw_resource_url (#2873)

- Fix DomainObject.count() to return count (#2919)

- Prevent unicode/ascii conversion errors in DataStore

- Fix datastore_delete erasing the db when filters is blank (#2885)

- Avoid package_search exception when using use_default_schema (#2848)

- resource_edit incorrectly setting action to new instead of edit
• Use ckan.site_url to generate urls of resources (#2592)
• Don’t hide actual exception on paster commands

8.42 v2.3.3 2015-12-17

Note: This version requires a requirements upgrade on source installations

Bug fixes:
• Fix Markdown rendering issue
• Return default error page on fanstatic errors
• Prevent authentication when using API callbacks

8.43 v2.3.2 2015-09-02

Bug fixes: * Fix autodetect for TSV resources (#2553) * Improve character escaping in DataStore parameters * Fix “paster db init” when celery is configured with a non-database backend

8.44 v2.3.1 2015-07-22

Bug fixes:
• Resource views won’t display when embedded in another site (#2238)
• resource_update failed if you supplied a revision_id (#2340)
• Recline could not plot GeoJSON on a map (#2387)
• Dataset create form 404 error if you added a resource but left it blank (#2392)
• Editing a resource view for a file that was UTF-8 and had a BOM gave an error (#2401)
• Email invites had the email address changed to lower-case (#2415)
• Default resource views not created when using a custom dataset schema (#2421, #2482)
• If the licenses pick-list was customized to remove some, datasets with old values had them overwritten when edited (#2472)
• Recline views failed on some non-ascii characters (#2490)
• Resource views for non-default dataset types couldn’t be created (#2532)

8.45 v2.3 2015-03-04

Note: This version requires a requirements upgrade on source installations

Note: This version requires a database upgrade

Note: This version requires a Solr schema upgrade

Note: This version requires a DataPusher upgrade on source installations. You should target DataPusher=>0.0.6 and upgrade its dependencies.
Major:

- Completely refactored resource data visualizations, allowing multiple persistent views of the same data
  an interface to manage and configure them. (#1251, #1851, #1852, #2204, #2205) Check the updated
documentation to know more, and the “Changes and deprecations” section for migration details:
  

- Responsive design for the default theme, that allows nicer rendering across different devices (#1935)

- Improved DataStore filtering and full text search capabilities (#1792, #1830, #1838, #1815)

- Added new extension points to modify the DataStore behaviour (#1725)

- Simplified two-step dataset creation process (#1659)

- Ability for users to regenerate their own API keys (#1412)

- New package_patch action to allow individual fields dataset updates (#1416, #1679)

- Changes on the authentication mechanism to allow more secure setups (httponly and secure cookies,
disable CORS, etc). (#2004, #2050, #2052 . . . ) See “Changes and deprecations” section for more details
  and “Troubleshooting” for migration instructions.

- Better support for custom dataset types (#1795, #2083)

- Extensions can combine free-form extras and convert_to_extras fields (#1894)

- Updated documentation theme, now clearer and responsive (#1845)

Minor:

- Adding custom fields tutorial (#790)

- Add metadata created and modified fields to the dataset page (#655)

- Improve IFacets plugin interface docstrings (#781)

- Remove help string from API calls (#1318)

- Add “datapusher submit” command to upload existing resources data (#1792)

- More template blocks to allow for easier extension maintenance (#1301)

- CKAN API - remove help string from standard calls (#1318)

- Hide activity by selected users on activity stream (#1330)

- Documentation and clarification about “CKAN Flavored Markdown” (#1332)

- Resource formats are now guessed automatically (#1350)

- New JavaScript modules tutorial (#1377)

- Allow overriding dataset, group, org validation (#1400)

- Remove ResourceGroups, show package_id on resources (#1407)

- Better errors for NAVL junk (#1418)

- DataPusher integration improvements (#1446)

- Allow people to create unowned datasets when they belong to an org (#1473)

- Add res_type to Solr schema (#1495)

- Separate data and metadata licenses on create dataset page (#1503)

- Allow CKAN (and paster) to find config from envvar (#1597)
• Added xlsx and tsv to the defaults for ckan.datapusher.formats. (#1644)
• Add resource extras to Solr search index (#1709)
• Prevent packages update in organization_update (#1711)
• Programatically log user in after registration (#1721)
• New plugin interfaces: IValidators.get_validators and IConverters.get_converters (#1841)
• Index resource name in Solr (#1905)
• Update search index after membership changes (#1917)
• resource_show: use package_show to get validated data (#1921)
• Serve placeholder images locally (#1951)
• Don’t get all datasets when loading the org in the dataset page (#1978)
• Text file preview - lack of vertical scroll bar for long files (#1982)
• Changes to allow better use of custom group types in IGroupForm extensions (#1987)
• Remove moderated edits (#2006)
• package_create: allow sysadmins to set package ids (#2102)
• Enable a logged in user to move dataset to another organization (#2218)
• Move PDF views into a separate extension (#2270)
• Do not provide email configuration in default config file (#2273)
• Add custom DataStore SQLAlchemy properties (#2279)

Bug fixes:
• Set up stats extension as namespace plugin (#291)
• Fix visibility validator for datasets (#1188)
• Select boxes with autocomplete are clearing their placeholders (#1278)
• Default search ordering on organization home page is broken (#1368)
• related_list logic function throws a 503 without any parameters (#1384)
• Exception on group dictize due to ‘with_capacity’ on context (#1390)
• Wrong template on Add member page (#1392)
• Overflowing email address on user page (#1398)
• The reset password e-mail is using an incorrect translation string (#1409)
• You can’t view a group when there is an IGroupForm (#1420)
• Disabling activity_streams borks editing groups and user (#1421)
• Use a more secure default for the repoze secret key (#1422)
• Duplicated Required Fields notice on Group form (#1426)
• UI language reset after account creation (#1429)
• num_followers and package_count not in default_group_schema (#1434)
• Fix extras deletion (#1449)
• Fix resource reordering (#1450)
• Datastore callback fails when browser url is different from site_url (#1451)
• sysadmins should not create datasets without org when config is set (#1453)
• Member Editing Fixes (#1454)
• Bulk editing broken on IE7 (#1455)
• Fix group deletion on IE7 (#1460)
• Organization ATOM feed is broken (#1463)
• Users can not delete a dataset that not belongs to an organization (#1471)
• Error during authorization in datapusher_hook (#1487)
• Wrong datapusher hook callback URL on non-root deployments (#1490)
• Wrong breadcrumbs on new dataset form and resource pages (#1491)
• Atom feed Content-Type returned as ‘text/html’ (#1504)
• Invite to organization causes Internal Server error (#1505)
• Dataset tags autocomplete doesn’t work (#1512)
• Activity Stream from: Organization Error group not found (#1519)
• Improve password hashing algorithm (#1530)
• Can’t download resources with geojson extension (#1534)
• All datasets for featured group/organization shown on home page (#1569)
• Able to list private datasets via the API (#1580)
• Don’t lowercase the names of uploaded files (#1584)
• Show more facets only if there are more facts to show (#1612)
• resource_create should break when called without URL (#1641)
• Creating a DataStore resource with the package_id fails for a normal user (#1652)
• Fix package permission checks for create+update (#1664)
• bulk_process page for non-existent organization throws Exception (#1682)
• Catch NotFound error in resource_proxy (#1684)
• Fix int_validator (#1692)
• Current date indexed on empty “_date” fields (#1701)
• Possible to show a resource inside an arbitrary dataset (#1707)
• Edit member page shows wrong fields (#1723)
• Insecure content warning when running Recline under SSL (#1729)
• Flash messages not displayed as part of page.html (#1743)
• package_show response includes solr rubbish when using ckan.cache_validated_datasets (#1764)
• “Add some resources” link shown to unauthorized users (#1766)
• email notifications via paster plugin post erroneously demands authentication (#1767)
• Inserting empty arrays in JSON type fields in datastore fails (#1776)
• Ordering a dataset listing loses the existing filters (#1791)
• Don’t delete all cookies whose names start with “ckan” (#1793)
• Upgrade some major requirements (eg SQLAlchemy, Requests) (#1817, #1819)
• list of member roles disappears on add member page (#1873)
• Stats plugin should only show active datasets (#1936)
• Featured group on homepage not linking to group (#1996)
• –reload doesn’t work on the ‘paster serve’ command (#2013)
• Can not override auth config options from tests (#2035)
• Fix resource_create authorization (#2037)
• package_search gives internal server error if page < 1 (#2042)
• Fix organization pagination (#2141)
• Resource extras can not be updated (#2158)
• package_show doesn’t validate when a custom schema is used (#2175)
• Update jQuery minified version to match the unminified one (#1750)
• Fix exception during database upgrade (#2029)
• Fix resources disappearing on dataset update (#1779)
• Fix activity stream queries performance on large instances (#2008)
• Only link to http, https and ftp resource urls (#2085)
• Avoid private and deleted datasets on stats plugin (#1936)
• Fix tags count and group links in stats extension (#1649)
• Make resource_create auth work against package_update (#2037)
• Fix DataStore permissions check on startup (#1374)
• Fix datastore docs link (#2044)
• Clean up field names before rendering the Recline table (#2319)
• Don’t “normalize” resource URL in recline view (#2324)
• Don’t assume resource format is there on text preview (#2320)
• And many, many more!

8.45.1 Changes and deprecations

• By convention, view plugin names now end with _view rather than _preview (eg recline_view rather than recline_preview). You will need to update them on the ckan.plugins setting.
• The way resource visualizations are created by default has changed. You might need to set the ckan.views.default_views configuration option and run a migration command on existing instances. Please refer to the migration guide for more details:

   http://docs.ckan.org/en/latest/maintaining/data-viewer.html#migrating-from-previous-ckan-versions

• The PDF Viewer extension has been moved to a separate extension: https://github.com/ckan/ckanext-pdfview. Please install it separately if you are using the pdf_view plugin (or the old pdf_preview one).
• The action API (v3) no longer returns the full help for the action on each request. It rather includes a link to a separate call to get the action help string.
• The user_show API call does not return the datasets, num_followers or activity keys by default any more.

Any custom templates or users of this API call that use these values will need to specify parameters: include_datasets or include_num_followers.

activity has been removed completely as it was actually a list of revisions, rather than the activity stream. If you want the actual activity stream for a user, call user_activity_list instead.

• The output of resource_show now contains a package_id key that links to the parent dataset.

• helpers.get_action() (or h.get_action() in templates) is deprecated.

Since action functions raise exceptions and templates cannot catch exceptions, it’s not a good idea to call action functions from templates.

Instead, have your controller method call the action function and pass the result to your template using the extra_vars param of render().

Alternatively you can wrap individual action functions in custom template helper functions that handle any exceptions appropriately, but this is likely to make your the logic in your templates more complex and templates are difficult to test and debug.

Note that logic.get_action() and toolkit.get_action() are not deprecated, core code and plugin code should still use get_action().

• Cross-Origin Resource Sharing (CORS) support is no longer enabled by default. Previously, Access-Control-Allow-* response headers were added for all requests, with Access-Control-Allow-Origin set to the wildcard value *. To re-enable CORS, use the new ckan.cors configuration settings (ckan.cors.origin_allow_all and ckan.cors.origin_whitelist).

• The HttpOnly flag will be set on the authorization cookie by default. For enhanced security, we recommend using the HttpOnly flag, but this behaviour can be changed in the Repoze.who settings detailed in the Config File Options documentation (who.httponly).

• The OpenID login option has been removed and is no longer supported. See “Troubleshooting” if you are upgrading an existing CKAN instance as you may need to update your who.ini file.

8.45.2 Template changes

• Note to people with custom themes: If you’ve changed the {% block secondary_content %} in templates/package/search.html pay close attention as this pull request changes the structure of that template block a little.

Also: There’s a few more bootstrap classes (especially for grid layout) that are now going to be in the templates. Take a look if any of the following changes might effect your content blocks:

https://github.com/ckan/ckan/pull/1935

8.45.3 Troubleshooting:

• Login does not work, for existing and new users.

You need to update your existing who.ini file.

– In the [plugin:auth_tkt] section, replace:

  use = ckan.config.middleware:ckan_auth_tkt_make_app

with:

use = ckan.config.middleware:ckan_auth_tkt_make_app
use = ckan.lib.auth_tkt:make_plugin

- In [authenticators], add the auth_tkt plugin

Also see the next point for OpenID related changes.

- Exception on first load after upgrading from a previous CKAN version:

```
ImportError: <module 'ckan.lib.authenticator' from '/usr/lib/ckan/default/src/ckan/ckan/lib/authenticator.py'> has no 'OpenIDAuthenticator' attribute
```

or:

```
ImportError: No module named openid
```

There are OpenID related configuration options in your who.ini file which are no longer supported. This file is generally located in /etc/ckan/default/who.ini but its location may vary if you used a custom deployment.

The options that you need to remove are:

- The whole [plugin:openid] section
- In [general], replace:

```
challenge_decider = repoze.who.plugins.openid.classifiers:openid_challenge_decider
```

with:

```
challenge_decider = repoze.who.classifiers:default_challenge_decider
```

- In [identifiers], remove openid
- In [authenticators], remove ckan.lib.authenticator:OpenIDAuthenticator
- In [challengers], remove openid

This is a diff with the whole changes:

https://github.com/ckan/ckan/pull/2058/files#diff-2

Also see the previous point for other who.ini changes.

---

**8.46 v2.2.4 2015-12-17**

Note: This version requires a requirements upgrade on source installations

*Bug fixes:*

- Fix Markdown rendering issue
- Return default error page on fanstatic errors
- Prevent authentication when using API callbacks
8.47 v2.2.3 2015-07-22

Bug fixes:

- Allow uppercase emails on user invites (#2415)
- Fix broken boolean validator (#2443)
- Fix auth check in resources_list.html (#2037)
- Key error on resource proxy (#2425)
- Ignore revision_id passed to resources (#2340)
- Add reset for reset_key on successful password change (#2379)

8.48 v2.2.2 2015-03-04

Bug fixes:

- Update jQuery minified version to match the unminified one (#1750)
- Fix exception during database upgrade (#2029)
- Fix resources disappearing on dataset upate (#1779)
- Fix activity stream queries performance on large instances (#2008)
- Only link to http, https and ftp resource urls (#2085)
- Avoid private and deleted datasets on stats plugin (#1936)
- Fix tags count and group links in stats extension (#1649)
- Make resource_create auth work against package_update (#2037)
- Fix DataStore permissions check on startup (#1374)
- Fix datastore docs link (#2044)
- Fix resource extras getting lost on resource update (#2158)
- Clean up field names before rendering the Recline table (#2319)
- Don’t “normalize” resource URL in recline view (#2324)
- Don’t assume resource format is there on text preview (#2320)

8.49 v2.2.1 2014-10-15

Bug fixes:

- Organization image_url is not displayed in the dataset view. (#1934)
- list of member roles disappears on add member page if you enter a user that doesn’t exist (#1873)
- group/organization_member_create do not return a value. (#1878)
- i18n: Close a tag in French translation in Markdown syntax link (#1919)
- organization_list_for_user() fixes (#1918)
- Don’t show private datasets to group members (#1902)
- Incorrect link in Organization snippet on dataset page (#1882)
- Prevent reading system tables on DataStore SQL search (#1871)
- Ensure that the DataStore is running on legacy mode when using PostgreSQL < 9.x (#1879)
- Select2 in the Tags field is broken (#1864)
- Edit user encoding error (#1436)
- Able to list private datasets via the API (#1580)
- Insecure content warning when running Recline under SSL (#1729)
- Add quotes to package ID in Solr query in _bulk_update_dataset to prevent Solr errors with custom dataset IDs. (#1853)
- Ordering a dataset listing loses the existing filters (#1791)
- Inserting empty arrays in JSON type fields in datastore fails (#1776)
- email notifications via pasteur plugin post erroneously demands authentication (#1767)
- “Add some resources” link shown to unauthorized users (#1766)
- Current date indexed on empty “*_date” fields (#1701)
- Edit member page shows wrong fields (#1723)
- programatically log user in after registration (#1721)
- Dataset tags autocomplete doesn’t work (#1512)
- Deleted Users bug (#1668)
- UX problem with previous and next during dataset creation (#1598)
- Catch NotFound error in resources page (#1685)
- _tracking page should only respond to POST (#1683)
- bulk_process page for non-existent organization throws Exception (#1682)
- Fix package permission checks for create+update (#1664)
- Creating a DataStore resource with the package_id fails for a normal user (#1652)
- Trailing whitespace in resource URLs not stripped (#1634)
- Move the closing div inside the block (#1620)
- Fix open redirect (#1419)
- Show more facets only if there are more facts to show (#1612)
- Fix breakage in package groups page (#1594)
- Fix broken links in RSS feed (#1589)
- Activity Stream from: Organization Error group not found (#1519)
- DataPusher and harvester collision (#1500)
- Can’t download resources with geojson extension (#1534)
- Oversized Forgot Password button and field (#1508)
- Invite to organization causes Internal Server error (#1505)
8.50 v2.2 2014-02-04

Note: This version does not require a requirements upgrade on source installations

Note: This version requires a database upgrade

Note: This version requires a Solr schema upgrade (The Solr schema file has been renamed, the schema file from the previous release is compatible with this version, but users are encouraged to point to the new one, see “API changes and deprecations”)

Major:

• Brand new automatic importer of tabular data to the DataStore, the DataPusher. This is much more robust and simple to deploy and maintain than its predecessor (ckanext-datastorer). Whole new UI for re-importing data to the DataStore and view the import logs (#932, #938, #940, #981, #1196, #1200 . . . )

• Completely revamped file uploads that allow closer integration with resources and the DataStore, as well as making easier to integrate file uploads in other features. For example users can now upload images for organizations and groups. See “API changes and deprecations” if you are using the current FileStore. (#1273, #1173 . . . )

• UI and API endpoints for resource reordering (#1277)

• Backend support for organization hierarchy, allowing parent and child organizations. Frontend needs to be implemented in extensions (#1038)

• User invitations: it is now possible to create new users with just their email address. An invite email is sent to them, allowing to change their username and password (#1178)

• Disable user registration with a configuration option (#1226)

• Great effort in improving documentation, specially for customizing CKAN, with a complete tutorial for writing extensions and customizing the theme. User and sysadmin guides have also been moved to the main documentation (#943, #847, #1253)

Minor:

• Homepage modules to allow predefined layouts (#1126)

• Ability to delete users (#1163)

• Dedicated dataset groups page for displaying and managing them (#1102)

• Implement organization_purge and group_purge action functions (#707)

• Improve package_show performance (#1078)

• Support internationalization of rendered dates and times (#1041)

• Improve plugin load handling (#549)

• Authorization function auditing for action functions (#1060)

• Improve datetime rendering (#518)

• New SQL indexes to improve performance (#1164)

• Changes in requirements management (#1149)

• Add offset/limit to package_list action (#1179)

• Document all available configuration options (#848)

• Make CKAN sqlalchemy 0.8.4 compatible (#1427)

• UI labelling and cleanup (#1030)
• Better UX for empty groups/orgs (#1094)
• Improve performance of group_dictize when the group has a lot of packages (#1208)
• Hide __extras from extras on package_show (#1218)
• “Clear all” link within each facet block is unnecessary (#1263)
• Term translations of organizations (#1274)
• ‘–reset-db’ option for when running tests (#1304)

Bug fixes:

• Fix plugins load/unload issues (#547)
• Improve performance when new_activities not needed (#1013)
• Resource preview breaks when CSV headers include percent sign (#1067)
• Package index not rebuilt when resources deleted (#1081)
• Don’t accept invalid URLs in resource proxy (#1106)
• UI language reset after account creation (#1429)
• Catch non-integer facet limits (#1118)
• Error when deleting custom tags (#1114)
• Organization images do not display on Organization user dashboard page (#1127)
• Can not reactivate a deleted dataset from the UI (#607)
• Non-existent user profile should give error (#1068)
• Recaptcha not working in CKAN 2.0 (jinja templates) (#1070)
• Groups and organizations can be visited with interchangeable URLs (#1180)
• Dataset Source (url) and Version fields missing (#1187)
• Fix problems with private / public datasets and organizations (#1188)
• group_show should never return private data (#1191)
• When editing a dataset, the organization field is not set (#1199)
• Fix resource_delete action (#1216)
• Fix trash purge action redirect broken for CKAN instances not at / (#1217)
• Title edit for existing dataset changes the URL (#1232)
• ‘facet.limit’ in package_search wrongly handled (#1237)
• h.SI_number_span doesn’t close <span /> correctly (#1238)
• CkanVersionException wrongly raised (#1241)
• (group|organization)_member_create only accepts username (and not id) (#1243)
• package_create uses the wrong parameter for organization (#1257)
• ValueError for non-int limit and offset query params (#1258)
• Visibility field value not kept if there are errors on the form (#1265)
• package_list should not return private datasets (#1295)
• Fix 404 on organization activity stream and about page (#1298)
• Fix placeholder images broken on non-root locations (#1309)
• “Add Dataset” button shown on org pages when not authorized (#1348)
• Fix exception when visiting organization history page (#1359)
• Fix search ordering on organization home page (#1368)
• datastore_search_sql failing for some anonymous users (#1373)
• related_list logic function throws a 503 without any parameters (#1384)
• Disabling activity_streams borks editing groups and user (#1421)
• Member Editing Fixes (#1454)
• Bulk editing broken in IE7 (#1455)
• Fix group deletion in IE7 (#1460)
• And many, many more!

API changes and deprecations:
• The Solr schema file is now always named schema.xml regardless of the CKAN version. Old schema files have been kept for backwards compatibility but users are encouraged to point to the new unified one (#1314)
• The FileStore and file uploads have been completely refactored and simplified to only support local storage backend. The links from previous versions of the FileStore to hosted files will still work, but there is a command available to migrate the files to new Filestore. See this page for more details: http://docs.ckan.org/en/latest/filestore.html#filestore-21-to-22-migration
• By default, the authorization for any action defined from an extension will require a logged in user, otherwise a ckan.logic.NotAuthorized exception will be raised. If an action function allows anonymous access (eg search, show status, etc) the auth_allow_anonymous_access decorator (available on the plugins toolkit) must be used (#1210)
• package_search now returns results with custom schemas applied like package_show, a use_default_schema parameter was added to request the old behaviour, this change may affect customized search result templates (#1255)
• The ckan.api_url configuration option has been completely removed and it can no longer be used (#960)
• The edit and after_update methods of IPackageController plugins are now called when updating a resource using the web frontend or the resource_update API action (#1052)
• Dataset moderation has been deprecated, and the code will probably be removed in later CKAN versions (#1139)
• Some front end libraries have been updated, this may affect existing custom themes: Bootstrap 2.0.3 > 2.3.2, Font Awesome 3.0.2 > 3.2.1, jQuery 1.7.2 > 1.10.2 (#1082)
• SQLite is officially no longer supported as the tests backend

Troubleshooting:
• Exception on startup after upgrading from a previous CKAN version:

```
AttributeError: 'instancemethod' object has no attribute 'auth_audit_exempt'
```

Make sure that you are not loading a 2.1-only plugin (eg datapusher-ext) and update all the plugin in your configuration file to the latest stable version.
• Exception on startup after upgrading from a previous CKAN version:
One of the database changes on this version is the addition of a `metadata_modified` field in the package table, that was filled during the DB migration process. If you have previously migrated the database and revert to an older CKAN version the migration process may have failed at this step, leaving the fields empty. Also make sure to restart running processes like harvesters after the update to make sure they use the new code base.

### 8.51 v2.1.6 2015-12-17

Note: This version requires a requirements upgrade on source installations

**Bug fixes:**

- Fix Markdown rendering issue
- Return default error page on fanstatic errors
- Prevent authentication when using API callbacks

### 8.52 v2.1.5 2015-07-22

**Bug fixes:**

- Fix broken boolean validator (#2443)
- Key error on resource proxy (#2425)
- Ignore revision_id passed to resources (#2340)
- Add reset for reset_key on successful password change (#2379)

### 8.53 v2.1.4 2015-03-04

**Bug fixes:**

- Only link to http, https and ftp resource urls (#2085)
- Avoid private and deleted datasets on stats plugin (#1936)
- Fix tags count and group links in stats extension (#1649)
- Make resource_create auth work against package_update (#2037)
- Fix DataStore permissions check on startup (#1374)
- Fix datastore docs link (#2044)
- Fix resource extras getting lost on resource update (#2158)
- Clean up field names before rendering the Recline table (#2319)
- Don’t “normalize” resource URL in recline view (#2324)
- Don’t assume resource format is there on text preview (#2320)
8.54 v2.1.3 2014-10-15

Bug fixes:

- Organization image_url is not displayed in the dataset view. (#1934)
- i18n: Close a tag in French translation in Markdown syntax link (#1919)
- organization_list_for_user() fixes (#1918)
- Incorrect link in Organization snippet on dataset page (#1882)
- Prevent reading system tables on DataStore SQL search (#1871)
- Ensure that the DataStore is running on legacy mode when using PostgreSQL < 9.x (#1879)
- Edit user encoding error (#1436)
- Able to list private datasets via the API (#1580)
- Insecure content warning when running Recline under SSL (#1729)
- Add quotes to package ID in Solr query in _bulk_update_dataset to prevent Solr errors with custom dataset IDs. (#1853)
- Ordering a dataset listing loses the existing filters (#1791)
- Inserting empty arrays in JSON type fields in datastore fails (#1776)
- programatically log user in after registration (#1721)
- Deleted Users bug (#1668)
- Catch NotFound error in resources page (#1685)

8.55 v2.1.2 2014-02-04

Bug fixes:

- Fix context for group/about setup_template_variables (#1433)
- Call setup_template_variables in group/org read, about and bulk_process (#1281)
- Remove repeated sort code in package_search (#1461)
- Ensure that check_access is called on activity_create (#1421)
- Fix visibility validator (#1188)
- Remove p.toolkit.auth_allow_anonymous_access as it is not available on 2.1.x (#1373)
- Add organization_revision_list to avoid exception on org history page (#1359)
- Fix activity and about organization pages (#1298)
- Show 404 instead of login page on user not found (#1068)
• Don’t show Add Dataset button on org pages unless authorized (#1348)
• Fix datastore_search_sql authorization function (#1373)
• Fix extras deletion (#1449)
• Better word breaking on long words (#1398)
• Fix activity and about organization pages (#1298)
• Remove limit of number of arguments passed to user add command.
• Fix related_list logic function (#1384)
• Avoid UnicodeEncodeError on feeds when params contains non ascii characters

8.56 v2.1.1 2013-11-8

Bug fixes:
• Fix errors on preview on non-root locations (#960)
• Fix place-holder images on non-root locations (#1309)
• Don’t accept invalid URLs in resource proxy (#1106)
• Make sure came_from url is local (#1039)
• Fix logout redirect in non-root locations (#1025)
• Wrong auth checks for sysadmins on package_create (#1184)
• Don’t return private datasets on package_list (#1295)
• Stop tracking failing when no lang/encoding headers (#1192)
• Fix for paster db clean command getting frozen
• Fix organization not set when editing a dataset (#1199)
• Fix PDF previews (#1194)
• Fix preview failing on private datastore resources (#1221)

8.57 v2.1 2013-08-13

Note: This version requires a requirements upgrade on source installations
Note: This version requires a database upgrade
Note: This version does not require a Solr schema upgrade

Note: The json_preview plugin has been renamed to text_preview (see #266). If you are upgrading CKAN from a previous version you need to change the plugin name on your CKAN config file after upgrading to avoid a PluginNotFound exception.

Major:
• Bulk updates of datasets within organizations (delete, make public/private) (#278)
• Organizations and Groups search (#303)
• Generic text preview extension for JSON, XML and plain text files (#226)
• Improve consistency of the Action API (#473)
• IAuthenticator interface for plugging into authorization platforms (Work in progress) (#1007)
• New clearer dashboard with more information easier to access (#626)
• New rebuild_fast command to speed up reindex using multiple cores (#700)
• Complete restructure of the documentation, with updated sections on installation, upgrading, release process, etc and guidelines on how to write new documentation (#769 and multiple others)

Minor:
• Add group members page to templates (#844)
• Show search facets on organization page (#776)
• Changed default sort ordering (#869)
• More consistent display of buttons across pages (#890)
• History page ported to new templates (#368)
• More blocks to templates to allow further customization (#688)
• Improve imports from lib.helpers (#262)
• Add support for callback parameter on Action API (#414)
• Create site_user at startup (#952)
• Add warning before deleting an organization (#803)
• Remove flags from language selector (#822)
• Hide the Data API button when datastore is disabled (#752)
• Pin all requirements and separate minimal requirements in a separate file (#491, #1149)
• Better requirements plugin selection (#1002)
• Add new preview plugin selection (#1015)
• Improve ExampleIDatasetFormPlugin (#2750)
• Extend h.sorted_extras() to do substitutions and auto clean keys (#440)
• Separate default database for development and testing (#517)
• More descriptive Solr exceptions when indexing (#674)
• Validate datastore input through schemas (#905)

Bug fixes:
• Fix 500 on password reset (#264)
• Fix exception when indexing a wrong date on a _date field (#267)
• Fix datastore permissions issues (#652)
• Placeholder images are not linked with h.url_for_static (#948)
• Explore dropdown menu is hidden behind other resources in IE (#915)
• Buttons interrupt file uploading (#902)
• Fix resource proxy encoding errors (#896)
• Enable streaming in resource proxy (#989)
• Fix cache_dir and beaker paths on deployment.ini_tmpl (#888)
• Fix multiple issues on create dataset form on IE (#881)
• Fix internal server error when adding member (#869)
• Fix license faceting (#853)
• Fix exception in dashboard (#830)
• Fix Google Analytics integration (#827)
• Fix ValueError when resource size is not an integer (#1009)
• Catch NotFound on new resource when package does not exist (#1010)
• Fix Celery configuration to allow overriding from config (#1027)
• came_from after login is validated to not redirect to another site (#1039)
• And many, many more!

Deprecated and removed:
• The json_preview plugin has been replaced by a new text_preview one. Please update your config files if using it. (#226)

Known issues:
• Under certain authorization setups the frontend for the groups functionality may not work as expected (See #1176 #1175).

8.58 v2.0.8 2015-12-17

Note: This version requires a requirements upgrade on source installations

Bug fixes:
• Fix Markdown rendering issue
• Return default error page on fanstatic errors
• Prevent authentication when using API callbacks

8.59 v2.0.7 2015-07-22

Bug fixes:
• Fix broken boolean validator (#2443)
• Key error on resource proxy (#2425)
• Ignore revision_id passed to resources (#2340)
• Add reset for reset_key on successful password change (#2379)
8.60 v2.0.6 2015-03-04

Bug fixes:

- Only link to http, https and ftp resource urls (#2085)
- Avoid private and deleted datasets on stats plugin (#1936)
- Fix tags count and group links in stats extension (#1649)
- Make resource_create auth work against package_update (#2037)
- Fix datastore docs link (#2044)
- Fix resource extras getting lost on resource update (#2158)
- Clean up field names before rendering the Recline table (#2319)
- Don’t “normalize” resource URL in recline view (#2324)
- Don’t assume resource format is there on text preview (#2320)

8.61 v2.0.5 2014-10-15

Bug fixes:

- organization_list_for_user() fixes (#1918)
- Incorrect link in Organization snippet on dataset page (#1882)
- Prevent reading system tables on DataStore SQL search (#1871)
- Ensure that the DataStore is running on legacy mode when using PostgreSQL < 9.x (#1879)
- Current date indexed on empty “_date” fields (#1701)
- Able to list private datasets via the API (#1580)
- Insecure content warning when running Recline under SSL (#1729)
- Inserting empty arrays in JSON type fields in datastore fails (#1776)
- Deleted Users bug (#1668)

8.62 v2.0.4 2014-02-04

Bug fixes:

- Fix extras deletion (#1449)
- Better word breaking on long words (#1398)
- Fix activity and about organization pages (#1298)
- Show 404 instead of login page on user not found (#1068)
- Remove limit of number of arguments passed to user add command.
- Fix related_list logic function (#1384)
8.63 v2.0.3 2013-11-8

Bug fixes:

- Fix errors on preview on non-root locations (#960)
- Don’t accept invalid URLs in resource proxy (#1106)
- Make sure came_from url is local (#1039)
- Fix logout redirect in non-root locations (#1025)
- Don’t return private datasets on package_list (#1295)
- Stop tracking failing when no lang/encoding headers (#1192)
- Fix for paster db clean command getting frozen

8.64 v2.0.2 2013-08-13

Bug fixes:

- Fix markdown in group descriptions (#303)
- Fix resource proxy encoding errors (#896)
- Fix datastore exception on first run (#907)
- Enable streaming in resource proxy (#989)
- Fix in user search (#1024)
- Fix Celery configuration to allow overriding from config (#1027)
- Undefined function on organizations controller (#1036)
- Fix license not translated in orgs/groups (#1040)
- Fix link to documentation from the footer (#1062)
- Fix missing close breadcrumb tag in org templates (#1071)
- Fix recently_changed_packages_activity_stream function (#1159)
- Fix Recline map sidebar not showing in IE 7-8 (#1133)

8.65 v2.0.1 2013-06-11

Bug fixes:

- Use IDatasetForm schema for resource_update (#897)
- Fixes for CKAN being run on a non-root URL (#948, #913)
- Fix resource edit errors losing info (#580)
- Fix Czech translation (#900)
- Allow JSON filters for datastore_search on GET requests (#917)
- Install vdm from the Python Package Index (#764)
- Allow extra parameters on Solr queries (#739)
• Create site user at startup if it does not exist (#952)
• Fix modal popups positioning (#828)
• Fix wrong redirect on dataset form on IE (#963)

8.66 v2.0 2013-05-10

Note: Starting on v2.0, issue numbers with four digits refer to the old ticketing system at http://trac.ckan.org and the ones with three digits refer to GitHub issues. For example:
• #3020 is http://trac.ckan.org/ticket/3020
• #271 is https://github.com/ckan/ckan/issues/271
Some GitHub issues URLs will redirect to GitHub pull request pages.

Note: v2.0 is a huge release so the changes listed here are just the highlights. Bug fixes are not listed.

Note: This version requires a requirements upgrade on source installations
Note: This version requires a database upgrade
Note: This version requires a Solr schema upgrade

Organizations based authorization (see Organizations and authorization): CKAN’s new “organizations” feature replaces the old authorization system with a new one based on publisher organizations. It replaces the “Publisher Profile and Workflow” feature from CKAN 1.X, any instances relying on it will need to be updated.
• New organization-based authorization and organization of datasets
• Supports private datasets
• Publisher workflow
• New authorization ini file options

New frontend (see Theming guide): CKAN’s frontend has been completely redesigned, inside and out. There is a new default theme and the template engine has moved from Genshi to Jinja2. Any custom templates using Genshi will need to be updated, although there is a ckan.legacy_templates setting to aid in the migration.
• Block-based template inheritance
• Custom jinja tags: {% ckan_extends %}, {% snippet %} and {% url_for %} (#2502, #2503)
• CSS “primer” page for theme developers
• We’re now using LESS for CSS
• Scalable font icons (#2563)
• Social sharing buttons (google plus, facebook, twitter) (this replaces the ckanext-social extension)
• Three-stage dataset creation form (#2501)
• New paster front-end-build command does everything needed to build the frontend for a production CKAN site (runs paster less to compile the css files, paster minify to minify the css and js files, etc.)

Plugins & Extensions:
• New plugins toolkit provides a stable set of utility and helper functions for CKAN plugins to depend on.
• The IDatasetForm plugin interface has been redesigned (note: this breaks backwards-compatibility with existing IDatasetForm plugins) (#649)
• Many IDatasetForm bugs were fixed
• New example extensions in core, and better documentation for the relevant plugin interfaces: example_itemtemplatehelpers (#447), example_idatasetform (#2750), hopefully more to come in 2.1!
• New IFacets interface that allows to modify the facets shown on various pages. (#400)
• The get_action() function now automatically adds ‘model’ and ‘session’ to the context dict (this saves on boiler-plate code, and means plugins don’t have to import ckan.model in order to call get_action()) (#172)

Activity Streams, Following & User Dashboard:

• New visual design for activity streams (#2941)
• Group activity streams now include activities for changes to any of the group’s datasets (#1664)
• Group activity streams now appear on group pages (previously they could only be retrieved via the api)
• Dataset activity streams now appear on dataset pages (previously they could only be retrieved via the api) (#3024)
• Users can now follow groups (previously you could only follow users or datasets) (#3005)
• Activity streams and following are also supported for organizations (#505)
• When you’re logged into CKAN, you now get a notifications count in the top-right corner of the site, telling you how many new notifications you have on your dashboard. Clicking on the count takes you to your dashboard page to view your notifications. (#3009)
• Optionally, you can also receive notifications by email when you have new activities on your dashboard (#1635)
• Infinite scrolling of activity streams (if you scroll to the bottom of a an activity stream, CKAN will automatically load more activities) (#3018)
• Redesigned user dashboard (#3028):
  – New dropdown-menu enables you to filter you dashboard activity stream to show only activities from a particular user, dataset, group or organization that you’re following
  – New sidebar shows previews and unfollow buttons (when the activity stream is filtered)
• New ckan.activity_streams_enabled config file setting allows you to disable the generation of activity streams (#654)

Data Preview:

• PDF files preview (#2203)
• JSON files preview
• HTML pages preview (in an iframe) (#2888)
• New plugin extension point that allows plugins to add custom data previews for different data types (#2961)
• Improved Recline Data Explorer previews (CSV files, Excel files..)
• Plain text files preview

API:

• The Action API is now CKAN’s default API, and the API documentation has been rewritten (#357)

Other highlights:
• CKAN now has continuous integration testing at https://travis-ci.org/ckan/ckan/
• Dataset pages now have <link rel="alternate" type="application/rdf+xml" links in the HTML headers, allows linked-data tools to find CKAN’s RDF rendering of a dataset’s metadata (#413)
• CKAN’s DataStore and Data API have been rewritten, and now use PostgreSQL instead of elasticsearch, so there’s no need to install elasticsearch anymore (this feature was also back-ported to CKAN 1.8) (#2733)
• New Config page for sysadmins (/ckan-admin/config) enables sysadmins to set the site title, tag line, logo, the intro text shown on the front page, the about text shown on the /about page, select a theme, and add custom CSS (#2302, #2781)
• New paster color command for creating color schemes
• Fanstatic integration (#2371):
  – CKAN now uses Fanstatic to specify required static resource files (js, css..) for web pages
  – Enables each page to only include the static files that it needs, reducing page loads
  – Enables CKAN to use bundled and minified static files, further reducing page loads
  – CKAN’s new paster minify command is used to create minified js and css files (#2950) (also see paster front-end-build)
• CKAN will now recognise common file format strings such as “application/json”, “JSON”, “.json” and “json” as a single file type “json” (#2416)
• CKAN now supports internalization of strings in javascript files, the new paster trans command is used to pull translatable strings out of javascript files (#2774, #2750)
• convert_to/from_extras have been fixed to not add quotes around strings (#2930)
• Updated CKAN coding standards (#3020) and CONTRIBUTING.rst file
• Built-in page view counting and ‘popular’ badges on datasets and resources There’s also a paster command to export the tracking data to a csv file (#195)
• Updated CKAN Coding Standards and new CONTRIBUTING.rst file
• You can now change the sort ordering of datasets on the dataset search page

Deprecated and removed:
• The IGenshiStreamFilter plugin interface is deprecated (#271), use the ITemplateHelpers plugin interface instead
• The Model, Search and Util APIs are deprecated, use the Action API instead
• Removed restrict_template_vars config setting (#2257)
• Removed deprecated facet_title() template helper function, use get_facet_title() instead (#2257)
• Removed deprecated am_authorized() template helper function, use check_access() instead (#2257)
• Removed deprecated datetime_to_datestr() template helper function (#2257)

8.67 v1.8.2 2013-08-13

Bug fixes:
• Fix for using harvesters with organization setup
• Refactor for user update logic
• Tweak resources visibility query

8.68 v1.8.1 2013-05-10

Bug fixes:
• Fixed possible XSS vulnerability on html input (#703)
• Fix unicode template 500 error (#808)
• Fix error on related controller

8.69 v1.8 2012-10-19

Note: This version requires a requirements upgrade on source installations
Note: This version requires a database upgrade
Note: This version does not require a Solr schema upgrade

Major
• New ‘follow’ feature that allows logged in users to follow other users or datasets (#2304)
• New user dashboard that shows an activity stream of all the datasets and users you are following. Thanks to Sven R. Kunze for his work on this (#2305)
• New version of the Datastore. It has been completely rewritten to use PostgreSQL as backend, it is more stable and fast and supports SQL queries (#2733)
• Clean up and simplifying of CKAN’s dependencies and source install instructions. Ubuntu 12.04 is now supported for source installs (#2428,#2592)
• Big speed improvements when indexing datasets (#2788)
• New action API reference docs, which individually document each function and its arguments and return values (#2345)
• Updated translations, added Japanese and Korean translations

Minor
• Add source install upgrade docs (#2757)
• Mark more strings for translation (#2770)
• Allow sort ordering of dataset listings on group pages (#2842)
• Reenable simple search option (#2844)
• Editing organization removes all datasets (#2845)
• Accessibility enhancements on templates

Bug fixes
• Fix for relative url being used when doing file upload to local storage
• Various fixes on IGroupFrom (#2750)
• Fix group dataset sort (#2722)
• Fix adding existing datasets to organizations (#2843)
• Fix 500 error in related controller (#2856)
• Fix for non-open licenses appearing open
• Editing organization removes all datasets (#2845)

API changes and deprecation:
• Template helper functions are now restricted by default. By default only those helper functions listed in lib.helpers.__allowed_functions__ are available to templates. The full functions can still be made available by setting ckan.restrict_template_vars = false in your ini file. Only restricted functions will be allowed in future versions of CKAN.
• Deprecated functions related to the old faceting data structure have been removed: helpers.py:facet_items(), facets.html:facet_sidebar(), facets.html:facet_list_items(). Internal use of the old facets datastructure (attached to the context, c.facets) has been superseded by use of the improved facet data structure, c.search_facets. The old data structure is still available on c.facets, but is deprecated, and will be removed in future versions. (#2313)

8.70  v1.7.4 2013-08-13

Bug fixes:
• Refactor for user update logic
• Tweak resources visibility query

8.71  v1.7.3 2013-05-10

Bug fixes:
• Fixed possible XSS vulnerability on html input (#703)

8.72  v1.7.2 2012-10-19

Minor:
• Documentation enhancements regarding file uploads

Bug fixes:
• Fixes for lincences i18n
• Remove sensitive data from user dict (#2784)
• Fix bug in feeds controller (#2869)
• Show dataset author and maintainer names even if they have no emails
• Fix URLs for some Amazon buckets
• Other minor fixes
**8.73 v1.7.1 2012-06-20**

**Minor:**

- Documentation enhancements regarding install and extensions (#2505)
- Home page and search results speed improvements (#2402,#2403)
- I18n: Added Greek translation and updated other ones (#2506)

**Bug fixes:**

- UI fixes (#2507)
- Fixes for i18n login and logout issues (#2497)
- Date on add/edit resource breaks if offset is specified (#2383)
- Fix in organizations read page (#2509)
- Add synchronous_search plugin to deployment.ini template (#2521)
- Inconsistent language on license dropdown (#2575)
- Fix bug in translating lists in multilingual plugin
- Group autocomplete doesn’t work with multiple words (#2373)
- Other minor fixes

**8.74 v1.7 2012-05-09**

**Major:**

- Updated SOLR schema (#2327). Note: This will require and update of the SOLR schema file and a reindex.
- Support for Organization based workflow, with membership determining access permissions to datasets (#1669,#2255)
- Related items such as visualizations, applications or ideas can now be added to datasets (#2204)
- Restricted vocabularies for tags, allowing grouping related tags together (#1698)
- Internal analytics that track number of views and downloads for datasets and resources (#2251)
- Consolidated multilingual features in an included extension (#1821,#1820)
- Atom feeds for publishers, tags and search results (#1593,#2277)
- RDF dump paster command (#2303)
- Better integration with the DataStore, based on ElasticSearch, with nice helper docs (#1797)
- Updated the Recline data viewer with new features such as better graphs and a map view (#2236,#2283)
- Improved and redesigned documentation (#2226,#2245,#2248)

**Minor:**

- Groups can have an image associated (#2275)
- Basic resource validation (#1711)
- Ability to search without accents for accented words (#906)
• Weight queries so that title is more important than rest of body (#1826)
• Enhancements in the dataset and resource forms (#1506)
• OpenID can now be disabled (#1830)
• API and forms use same validation (#1792)
• More robust bulk search indexing, with options to ignore exceptions and just refresh (#1616i,#2232)
• Modify where the language code is placed in URLs (#2261)
• Simplified licenses list (#1359)
• Add extension point for dataset view (#1741)

**Bug fixes:**

• Catch exceptions on the QA archiver (#1809)
• Error when changing language when CKAN is mounted in URL (#1804)
• Naming of a new package/group can clash with a route (#1742)
• Can’t delete all of a package’s resources over REST API (#2266)
• Group edit form didn’t allow adding multiple datasets at once (#2292)
• Fix layout bugs in IE 7 (#1788)
• Bug with Portuguese translation and Javascript (#2318)
• Fix broken parse_rfc_2822 helper function (#2314)

### 8.75 v1.6 2012-02-24

**Major:**

• Resources now have their own pages, as well as showing in the Dataset (#1445, #1449)
• Group pages enhanced, including in-group search (#1521)
• User pages enhanced with lists of datasets (#1396) and recent activity (#1515)
• Dataset view page decluttered (#1450)
• Tags not restricted to just letters and dashes (#1453)
• Stats Extension and Storage Extension moved into core CKAN (#1576, #1608)
• Ability to mounting CKAN at a sub-URL (#1401, #1659)
• 5 Stars of Openness ratings show by resources, if ckanext-qa is installed (#1583)
• Recline Data Explorer (for previewing and plotting data) improved and v2 moved into core CKAN (#1602, #1630)

**Minor:**

• ‘About’ page rewritten and easily customisable in the config (#1626)
• Gravatar picture displayed next to My Account link (#1528)
• ‘Delete’ button for datasets (#1425)
• Relationships API more RESTful, validated and documented (#1695)
• User name displayed when logged in (#1529)
• Database dumps now exclude deleted packages (#1623)
• Dataset/Tag name length now limited to 100 characters in API (#1473)
• ‘Status’ API call now includes installed extensions (#1488)
• Command-line interface for list/read/deleting datasets (#1499)
• Slug API calls tidied up and documented (#1500)
• Users nagged to add email address if missing from their account (#1413)
• Model and API for Users to become Members of a Group in a certain Capacity (#1531, #1477)
• Extension interface to adjust search queries, indexing and results (#1547, #1738)
• API for changing permissions (#1688)

Bug fixes:
• Group deletion didn’t work (#1536)
• metadata_created used to return an entirely wrong date (#1546)
• Unicode characters in field-specific API search queries caused exception (since CKAN 1.5) (#1798)
• Sometimes task_status errors weren’t being recorded (#1483)
• Registering or Logging in failed silently when already logged in (#1799)
• Deleted packages were browseable by administrators and appeared in dumps (#1283, #1623)
• Facicon was a broken link unless corrected in config file (#1627)
• Dataset search showed last result of each page out of order (#1683)
• ‘Simple search’ mode showed 0 packages on home page (#1709)
• Occasionally, ‘My Account’ shows when user is not logged in (#1513)
• Could not change language when on a tag page that had accented characters or dataset creation page (#1783, #1791)
• Editing package via API deleted its relationships (#1786)

8.76 v1.5.1 2012-01-04

Major:
• Background tasks (#1363, #1371, #1408)
• Fix for security issue affecting CKAN v1.5 (#1585)

Minor:
• Language support now excellent for European languages: en de fr it es no sv pl ru pt cs sr ca

• Web UI improvements:
  – Resource editing refreshed
  – Group editing refreshed
  – Indication that group creation requires logging-in (#1004)
  – Users’ pictures displayed using Gravatar (#1409)
  – ‘Welcome’ banner shown to new users (#1378)
Group package list now ordered alphabetically (#1502)

- Allow managing a dataset’s groups also via package entity API (#1381)
- Dataset listings in API standardised (#1490)
- Search ordering by modification and creation date (#191)
- Account creation disallowed with Open ID (create account in CKAN first) (#1386)
- User name can be modified (#1386)
- Email address required for registration (for password reset) (#1319)
- Atom feeds hidden for now
- New config options to ease CSS insertion into the template (#1380)
- Removed ETag browser cache headers (#1422)
- CKAN version number and admin contact in new ‘status_show’ API (#1087)
- Upgrade SQLAlchemy to 0.7.3 (compatible with Postgres up to 9.1) (#1433)
- SOLR schema is now versioned (#1498)

**Bug fixes:**

- Group ordering on main page was alphabetical but should be by size (since 1.5) (#1487)
- Package could get added multiple times to same Group, distorting Group size (#1484)
- Search index corruption when multiple CKAN instances on a server all storing the same object (#1430)
- Dataset property metadata_created had wrong value (since v1.3) (#1546)
- Tag browsing showed tags for deleted datasets (#920)
- User name change field validation error (#1470)
- You couldn’t edit a user with a unicode email address (#1479)
- Package search API results missed the extra fields (#1455)
- OpenID registration disablement explained better (#1532)
- Data upload (with ckanext-storage) failed if spaces in the filename (#1518)
- Resource download count fixed (integration with ckanext-googleanalytics) (#1451)
- Multiple CKANs with same dataset IDs on the same SOLR core would conflict (#1462)

**8.77 v1.5 2011-11-07**

**Deprecated due to security issue #1585**

**Major:**

- New visual theme (#1108)
  - Package & Resource edit overhaul (#1294/#1348/#1351/#1368/#1296)
  - JS and CSS reorganization (#1282, #1349, #1380)
- Apache Solr used for search in core instead of Postgres (#1275, #1361, #1365)
- Authorization system now embedded in the logic layer (#1253)
CKAN documentation, Release 2.8.5

- Captcha added for user registration (#1307, #1431)
- UI language translations refreshed (#1292, #1350, #1418)
- Action API improved with docs now (#1315, #1302, #1371)

Minor:

- Cross-Origin Resource Sharing (CORS) support (#1271)
- Strings to translate into other languages tidied up (#1249)
- Resource format autocomplete (#816)
- Database disconnection gives better error message (#1290)
- Log-in cookie is preserved between sessions (#78)
- Extensions can access formAlchemy forms (#1301)
- ‘Dataset’ is the new name for ‘Package’ (#1293)
- Resource standard fields added: type, format, size (#1324)
- Listing users speeded up (#1268)
- Basic data preview functionality moved to core from QA extension (#1357)
- Admin Extension merged into core CKAN (#1264)
- URLs in the Notes field are automatically linked (#1320)
- Disallow OpenID for account creation (but can be linked to accounts) (#1386)
- Tag name now validated for max length (#1418)

Bug fixes:

- Purging of revisions didn’t work (since 1.4.3) (#1258)
- Search indexing wasn’t working for SOLR (since 1.4.3) (#1256)
- Configuration errors were being ignored (since always) (#1172)
- Flash messages were temporarily held-back when using proxy cache (since 1.3.2) (#1321)
- On login, user told ‘welcome back’ even if he’s just registered (#1194)
- Various minor exceptions cropped up (mostly since 1.4.3) (#1343, #1346)
- Extra field couldn’t be set to original value when key deleted (#1356)
- JSONP callback parameter didn’t work for the Action API (since 1.4.3) (#1437)
- The same tag could be added to a package multiple times (#1331)

8.78 v1.4.3.1 2011-09-30

Minor:

- Added files to allow debian packaging of CKAN
- Added Catalan translation

Bug fixes:

- Incorrect Group creation form parameter caused exception (#1347)
• Incorrect AuthGroup creation form parameter caused exception (#1346)

8.79 v1.4.3 2011-09-13

Major:
• Action API (API v3) (beta version) provides powerful RPC-style API to CKAN data (#1335)
• Documentation overhaul (#1142, #1192)

Minor:
• Viewing of a package at a given date (as well as revision) with improved UI (#1236)
• Extensions can now add functions to the logic layer (#1211)
• Refactor all remaining database code out of the controllers and into the logic layer (#1229)
• Any OpenID log-in errors that occur are now displayed (#1228)
• ‘url’ field added to search index (e9214)
• Speed up tag reading (98d72)
• Cope with new WebOb version 1 (#1267)
• Avoid exceptions caused by bots hitting error page directly (#1176)
• Too minor to mention: #1234,

Bug fixes:
• Re-adding tags to a package failed (since 1.4.1 in Web UI, 1.4 in API) (#1239)
• Modified revisions retrieved over API caused exception (since 1.4.2) (#1310)
• Whichever language you changed to, it announced “Language set to: English” (since 1.3.1) (#1082)
• Incompatibilities with Python 2.5 (since 1.3.4.1 and maybe earlier) (#1325)
• You could create an authorization group without a name, causing exceptions displaying it (#1323)
• Revision list wasn’t showing deleted packages (b21f4)
• User editing error conditions handled badly (#1265)

8.80 v1.4.2 2011-08-05

Major:
• Packages revisions can be marked as ‘moderated’ (#1141, #1147)
• Password reset facility (#1186/#1198)

Minor:
• Viewing of a package at any revision (#1236)
• API POSTs can be of Content-Type “application/json” as alternative to existing “application/x-www-form-urlencoded” (#1206)
• Caching of static files (#1223)

Bug fixes:
• When you removed last row of resource table, you couldn’t add it again - since 1.0 (#1215)
• Adding a tag to package that had it previously didn’t work - since 1.4.1 in UI and 1.4.0 in API (#1239)
• Search index was not updated if you added a package to a group - since 1.1 (#1140)
• Exception if you had any Groups and migrated between CKAN v1.0.2 to v1.2 (migration 29) - since v1.0.2 (#1205)
• API Package edit requests returned the Package in a different format to usual - since 1.4 (#1214)
• API error responses were not all JSON format and didn’t have correct Content-Type (#1214)
• API package delete doesn’t require a Content-Length header (#1214)

8.81 v1.4.1 2011-06-27

Major:
• Refactor Web interface to use logic layer rather than model objects directly. Forms now defined in navl schema and designed in HTML template. Forms use of Formalchemy is deprecated. (#1078)

Minor:
• Links in user-supplied text made less attractive to spammers (nofollow) #1181
• Package change notifications - remove duplicates (#1149)
• Metadata dump linked to (#1169)
• Refactor authorization code to be common across Package, Group and Authorization Group (#1074)

Bug fixes
• Duplicate authorization roles were difficult to delete (#1083)

8.82 v1.4 2011-05-19

Major:
• Authorization forms now in grid format (#1074)
• Links to RDF, N3 and Turtle metadata formats provided by semantic.ckan.net (#1088)
• Refactor internal logic to all use packages in one format - a dictionary (#1046)
• A new button for administrators to change revisions to/from a deleted state (#1076)

Minor:
• Etags caching can now be disabled in config (#840)
• Command-line tool to check search index covers all packages (#1073)
• Command-line tool to load/dump postgres database (#1067)

Bug fixes:
• Visitor can’t create packages on new CKAN install - since v1.3.3 (#1090)
• OpenID user pages couldn’t be accessed - since v1.3.2 (#1056)
• Default site_url configured to ckan.net, so pages obtains CSS from ckan.net- since v1.3 (#1085)
8.83 v1.3.3 2011-04-08

Major:

- Authorization checks added to editing Groups and PackageRelationships (#1052)
- API: Added package revision history (#1012, #1071)

Minor:

- API can take auth credentials from cookie (#1001)
- Theming: Ability to set custom favicon (#1051)
- Importer code moved out into ckanext-importlib repo (#1042)
- API: Group can be referred to by ID (in addition to name) (#1045)
- Command line tool: rights listing can now be filtered (#1072)

Bug fixes:

- SITE_READ role setting couldn’t be overridden by sysadmins (#1044)
- Default ‘reader’ role too permissive (#1066)
- Resource ordering went wrong when editing and adding at same time (#1054)
- GET followed by PUTting a package stored an incorrect license value (#662)
- Sibling package relationships were shown for deleted packages (#664)
- Tags were displayed when they only apply to deleted packages (#920)
- API: ‘Last modified’ time was localised - now UTC (#1068)

8.84 v1.3.2 2011-03-15

Major:

- User list in the Web interface (#1010)
- CKAN packaged as .deb for install on Ubuntu
- Resources can have extra fields (although not in web interface yet) (#826)
- CSW Harvesting - numerous of fixes & improvements. Ready for deployment. (#738 etc)
- Language switcher (82002)

Minor:

- Wordpress integration refactored as a Middleware plugin (#1013)
- Unauthorized actions lead to a flash message (#366)
- Resources Groups to group Resources in Packages (#956)
- Plugin interface for authorization (#1011)
- Database migrations tested better and corrected (#805, #998)
- Government form moved out into ckanext-dgu repo (#1018)
- Command-line user authorization tools extended (#1038, #1026)
- Default user roles read from config file (#1039)
Bug fixes:

• Mounting of filesystem (affected versions since 1.0.1) (#1040)
• Resubmitting a package via the API (affected versions since 0.6?) (#662)
• Open redirect (affected v1.3) (#1026)

8.85 v1.3 2011-02-18

http://ckan.org/milestone/ckan-v1.3

Highlights of changes:

• Package edit form improved:
  – field instructions (#679)
  – name autofilled from title (#778)
• Group-based access control - Authorization Groups (#647)
• Metadata harvest job management (#739, #884, #771)
• CSW harvesting now uses owslib (#885)
• Package creation authorization is configurable (#648)
• Read-only maintenance mode (#777)
• Stats page (#832) and importer (#950) moved out into CKAN extensions

Minor:

• site_title and site_description config variables (#974)
• Package creation/edit timestamps (#806)
• Caching configuration centralised (#828)
• Command-line tools - sysadmin management (#782)
• Group now versioned (#231)

8.86 v1.2 2010-11-25

http://ckan.org/milestone/ckan-v1.2

Highlights of changes:

• Package edit form: attach package to groups (#652) & revealable help
• Form API - Package/Harvester Create/New (#545)
• Authorization extended: user groups (#647) and creation of packages (#648)
• Plug-in interface classes (#741)
• WordPress twentyten compatible theming (#797)
• Caching support (ETag) (#693)
• Harvesting GEMINI2 metadata records from OGC CSW servers (#566)

Minor:
• New API key header (#466)
• Group metadata now revisioned (#231)

8.87 v1.1 2010-08-10

http://ckan.org/milestone/v1.1

Highlights of changes:
• Changes to the database cause notifications via AMQP for clients (#325)
• Pluggable search engines (#317), including SOLR (#353)
• API is versioned and packages & groups can be referred to by invariant ID (#313)
• Resource search in API (#336)
• Visual theming of CKAN now easy (#340, #320)
• Greater integration with external Web UIs (#335, #347, #348)
• Plug-ins can be configured to handle web requests from specified URIs and insert HTML into pages.

Minor:
• Search engine optimisations e.g. alphabetical browsing (#350)
• CSV and JSON dumps improved (#315)

8.88 v1.0.2 2010-08-27

• Bugfix: API returns error when creating package (#432)

8.89 v1.0.1 2010-06-23

Functionality:
• API: Revision search 'since id' and revision model in API
• API: Basic API versioning - packages specified by ID (#313)
• Pluggable search - initial hooks
• Customisable templates (#340) and external UI hooks (#335)

Bugfixes:
• Revision primary key lost in migrating data (#311)
• Local authority license correction in migration (#319)
• I18n formatting issues
• Web i/f searches foreign characters (#319)
• Data importer timezone issue (#330)
**8.90 v1.0 2010-05-11**

CKAN comes of age, having been used successfully in several deployments around the world. 56 tickets covered in this release. See: [http://ckan.org/milestone/v1.0](http://ckan.org/milestone/v1.0)

Highlights of changes:

- Package edit form: new pluggable architecture for custom forms (#281, #286)
- Package revisions: diffs now include tag, license and resource changes (#303)
- Web interface: visual overhaul (#182, #206, #214-#227, #260) including a tag cloud (#89)
- i18n: completion in Web UI - now covers package edit form (#248)
- API extended: revisions (#251, #265), feeds per package (#266)
- Developer documentation expanded (#289, #290)
- Performance improved and CKAN stress-tested (#201)
- Package relationships (Read-Write in API, Read-Only in Web UI) (#253-257)
- Statistics page (#184)
- Group edit: add multiple packages at once (#295)
- Package view: RDF and JSON formatted metadata linked to from package page (#247)

Bugfixes:

- Resources were losing their history (#292)
- Extra fields now work with spaces in the name (#278, #280) and international characters (#288)
- Updating resources in the REST API (#293)

Infrastructural:

- Licenses: now uses external License Service (‘licenses’ Python module)
- Changesets introduced to support distributed revisioning of CKAN data - see doc/distributed.rst for more information.

**8.91 v0.11 2010-01-25**

Our biggest release so far (55 tickets) with lots of new features and improvements. This release also saw a major new production deployment with the CKAN software powering [http://data.gov.uk/](http://data.gov.uk/) which had its public launch on Jan 21st!

For a full listing of tickets see: [http://ckan.org/milestone/v0.11](http://ckan.org/milestone/v0.11). Main highlights:

- Package Resource object (multiple download urls per package): each package can have multiple ‘resources’ (urls) with each resource having additional metadata such as format, description and hash (#88, #89, #229)
- “Full-text” searching of packages (#187)
- Semantic web integration: RDFization of all data plus integration with an online RDF store (e.g. for [http://www.ckan.net/](http://www.ckan.net/) at [http://semantic.ckan.net/](http://semantic.ckan.net/) or Talis store) (#90 #163)
- Package ratings (#77 #194)
- Package diffs available in package history (#173)
• Minor:
  – Package undelete (#21, #126)
  – Automated CKAN deployment via Fabric (#213)
  – Listings are sorted alphabetically (#195)
  – Add extras to rest api and to ckanclient (#158 #166)
• Infrastructural:
  – Change to UUIDs for revisions and all domain objects
  – Improved search performance and better pagination
  – Significantly improved performance in API and WUI via judicious caching

8.92 v0.10 2009-09-30

• Switch to repoze.who for authentication (#64)
• Explicit User object and improved user account UI with recent edits etc (#111, #66, #67)
• Generic Attributes for Packages (#43)
• Use sqlalchmey-migrate to handle db/model upgrades (#94)
• “Groups” of packages (#105, #110, #130, #121, #123, #131)
• Package search in the REST API (#108)
• Full role-based access control for Packages and Groups (#93, #116, #114, #115, #117, #122, #120)
• New CKAN logo (#72)
• Infrastructural:
  – Upgrade to Pylons 0.9.7 (#71)
  – Convert to use formalchemy for all forms (#76)
  – Use paginate in webhelpers (#118)
• Minor:
  – Add author and maintainer attributes to package (#91)
  – Change package state in the WUI (delete and undelete) (#126)
  – Ensure non-active packages don’t show up (#119)
  – Change tags to contain any character (other than space) (#62)
  – Add Is It Open links to package pages (#74)

8.93 v0.9 2009-07-31

• (DM!) Add version attribute for package
• Fix purge to use new version of vdm (0.4)
• Link to changed packages when listing revision
• Show most recently registered or updated packages on front page
• Bookmarklet to enable easy package registration on CKAN
• Usability improvements (package search and creation on front page)
• Use external list of licenses from license repository
• Convert from py.test to nosetests

8.94 v0.8 2009-04-10

• View information about package history (ticket:53)
• Basic datapkg integration (ticket:57)
• Show information about package openness using icons (ticket:56)
• One-stage package create/registration (r437)
• Reinstate package attribute validation (r437)
• Upgrade to vdm 0.4

8.95 v0.7 2008-10-31

• Convert to use SQLAlchemy and vdm v0.3 (v. major)
• Atom/RSS feed for Recent Changes
• Package search via name and title
• Tag lists show number of associated packages

8.96 v0.6 2008-07-08

• Autocompletion (+ suggestion) of tags when adding tags to a package.
• Paginated lists for packages, tags, and revisions.
• RESTful machine API for package access, update, listing and creation.
• API Keys for users who wish to modify information via the REST API.
• Update to vdm v0.2 (SQLObject) which fixes ordering of lists.
• Better immunity to SQL injection attacks.

8.97 v0.5 2008-01-22

• Purging of a Revision and associated changes from cli and wui (ticket:37)
• Make data available in machine-usable form via sql dump (ticket:38)
• Upgrade to Pylons 0.9.6.* and deploy (ticket:41)
• List and search tags (ticket:33)
• (bugfix) Manage reserved html characters in urls (ticket:40)
• New spam management utilities including (partial) blacklist support

8.98 v0.4 2007-07-04

• Preview support when editing a package (ticket:36).
• Correctly list IP address of of not logged in users (ticket:35).
• Improve read action for revision to list details of changed items (r179).
• Sort out deployment using modpython.

8.99 v0.3 2007-04-12

• System now in a suitable state for production deployment as a beta
• Domain model versioning via the vdm package (currently released separately)
• Basic Recent Changes listing log messages
• User authentication (login/logout) via open ID
• License page
• Myriad of small fixes and improvements

8.100 v0.2 2007-02

• Complete rewrite of ckan to use pylons web framework
• Support for full CRUD on packages and tags
• No support for users (authentication)
• No versioning of domain model objects

8.101 v0.1 2006-05

NB: not an official release
• Almost functional system with support for persons, packages
• Tag support only half-functional (tags are per package not global)
• Limited release and file support
